QUALITY & PRICE
CUSHCRAFT ANTENNAS OFFER YOU BOTH

Don't be misled by our prices... they are based on experience, large quantity buying of materials, great engineering and efficient office personnel. We are happy here trying to hold the line on prices for you. So... why pay more when you can get the best for less!

FM 2 METER ANTENNAS

FM TWIST
Ten elements horizontal polarization for low end coverage and ten elements vertical polarization for FM coverage. For OSCAR buffs we have 144 MHz and 432 MHz models.

POWER PACK
The big signal (22 element array) for 2 meter FM uses two A147-11 yagis with a horizontal mounting boom, coaxial harness and all hardware.

4-6-11 ELEMENT YAGIS
The standard of comparison in VHF-UHF communications, now cut for FM and vertical polarization. There are models covering the 450 MHz, 220 MHz and 147 MHz bands. All are rated at 1000 watts with direct 52 ohm feed and PL 259 connectors.

IN STOCK WITH YOUR LOCAL DISTRIBUTOR

CUSHCRAFT CORPORATION
621 HAYWARD ST., MANCHESTER, N.H. 03103
for those who demand the finest

the completely new
MODEL CX-11 ... Deluxe Integrated Station

Many New Features

New solid state broadband linear power amplifier 10-160 meters. 360 watts input — requires no tuning — completely self-protected.

New concept front-end design — utilizing TWO revolutionary double active quad J-FET balanced mixers — for the ultimate in cross-mod, inter-mod, and overload prevention.

Solid-state modular construction utilizing gold-plated, pins and plug-in sockets for all transistors, IC's, and circuit board connectors.

Five bandwidths of selectivity are standard — 2.4, 1.5, 1.0, .4, .1 kHz.

Peak notch filter with adjustable notch and peak frequency.

RTTY narrow and wide shift FSK-LSB.

Built-in electronic Keyer with independent speed and weight control and partial or full dot memory.

Built-in Power Supply completely self-protecting — both thermal and current overload, integrated circuit controlled.

New six-digit frequency counter utilizing new ½ inch LED's optimized for a non-blinking, stable display.

ADDITIONAL FEATURES

Dual VFO's for transceive, split operation, or dual receive.

Adjustable IF shift.

Receive or transmit offset tuning.

Push Button spotting.

Adjustable R.F. clipping.

Instantaneous break-in CW.

Built-in Wattmeter.

Built-in noise blanker.

Adjustable R.F. power output.

Pre-IF, adjustable noise blanker.

Now in production at $2900

The perfect power meter

The R&S Model NAUS80-A outperforms the BIRD at a lower price...

...from 25-525 MHz; 1000 MHz (useable) 20 mW-320W.
Check the comparison below and see for yourself.

R&S — NAUS80-A

- High Resolution — linear scale
- High Accuracy — 4% of reading ±1% full scale
- Simultaneous incident and reflected power reading (VSWR) (with two separate meters) provides optimized performance and time savings
- 5 YEAR WARRANTY ON PARTS & LABOR
- 1 kW overload protection
- 1 head for ALL frequencies and power ranges, no plug-in elements required — also one low price.

BIRD

- Compressed log... See for yourself
- 5% Full Scale (% of reading not specified!!!)
- One meter readings make it almost impossible to optimize performance and its extremely time consuming
- 1 year and it excludes semiconductors, tubes, fuses, etc. Ask them for a copy of their warranty... you'll be amazed.
- No overload protection — expensive elements can easily burn out.
- Over 30 plug-in elements to achieve the same power/frequency ranges — this more than doubles the R&S price.

Power measurement of amateur transmitters is a serious topic of discussion at the FCC these days. Although the amateur restructuring proposal, Docket 20282, has proposed that the maximum transmitter output power shall not exceed 2000 watts peak envelope power, a footnote points out that this is only one proposal under consideration by the FCC. The Commission is also looking at alternatives such as PEP input, average power input, ratios of peak to average power output, limitations on the dissipation ratings of final power amplifier devices or even a combination of these.

Prose Walker, W4BW, Chief of the Amateur and Citizens’ Division, is soliciting suggestions for solutions to this problem, and doesn’t want to wait for the Docket comments to hear your ideas. A note to him at 2025 M Street, NW, Washington, DC 20554, with your recommendation, would be appreciated.

Although some amateurs may feel that it makes little difference whether the regulations specify input or output power, at frequencies above 50 MHz or so, where operating efficiencies are much lower, it is extremely important. On the high-frequency amateur bands typical transmitter efficiency is on the order of 70 per cent, but at vhf and uhf efficiency can drop to 50 per cent or even less. That 20 per cent difference can make a considerable difference to the vhf'er who is trying to extend his communications range. And, with the rf wattmeters which are currently available, there seems to be little reason why the amateur power limitations shouldn’t be expressed in terms of output power.

Until relatively recently, the accurate measurement of high-frequency rf power required very expensive instruments to which few amateurs had access: matched dummy loads, calorimeters and other thermal devices which could be calibrated with known dc voltages and currents. Furthermore, the difficulty of rf power measurements increased with both frequency and power level. Accurate measurement of 500 watts output, for example, was many times more difficult than the measurement of 50 watts output, even on the hf bands. These measurements were further complicated at vhf and uhf, and accurate measurement of the output of high-power vhf transmitters was virtually impossible.

The introduction of toroidal-type directional wattmeters about fifteen years ago solved the problem of high-frequency average power measurement (subsequent design improvements have moved the frequency range up to 250 MHz or so), but the difficulty of measuring peak envelope power still remains. At least one coupler (the Collins 302C) added a capacitor to the circuit to make it more of a peak-reading device, but it still reads only about 65 per cent of the actual peaks. Most other types of wattmeters, including absorption types and the popular Bird model 43, theoretically read 40.5 per cent of the actual peak power of a two-frequency signal. The Bird model 4311 reads peak power directly, but it’s priced out of the range of most amateurs. However, it should be fairly simple to design a peak-reading amplifier for use with average-reading rf wattmeters that would provide direct measurements of peak envelope power.

Another possibility is the use of a single-tone. Single-tone modulation of a ssb transmitter results in peak envelope power output which equals average power and is indicated correctly on average-reading power rf power meters. However, this technique is not nearly as tidy as a peak-reading rf wattmeter which is always in the line.

WE'VE GIVEN IT A NEW LOOK!

IC-22A

The front panel and control locations have been changed to make the IC-22A even better looking and easier to operate. The new design allows the use of larger channel numbers which may be viewed from the left side or right side by reversing the window position and installing a new dial (optional at nominal cost)

Inside is the same high quality radio construction and engineering that has made the IC-22 the most reliable, most popular two meter crystal controlled set on the market.

When you join 22 channels of capacity (five supplied) with the unexcelled performance of helical RF filtering in the receiver front end then add solid state T-R switching you get one great radio for your money. All the great features that made the IC-22 so desired are still there. Including, 1 watt/10 watt switch option, trimmer capacitors on both receiver and transmitter crystals plus a 9 pin accessory jack with the discriminator already wired for frequency calibration

SEE ONE!! BUY ONE!! AT YOUR ICOM DEALER TODAY.
BICENTENNIAL CALLSIGN SCHEME has been released, and as expected, all FCC-licensed amateurs can have some fun with it in 1976 if they're so inclined. State-side alternate prefixes are straightforward, with WA becoming AA, W changing to AC, and repeaters getting an optional AF.

Outside The Contiguous U.S. is where the fun really begins, however, with Samoa becoming AH3 and an Alaskan Novice an AL1. The partial scheme appears below. Don't rush to cut it out because we'll include a larger scale chart later this year.

Use Of The Alternate Prefixes is entirely optional and no paperwork will be required. Just remember they don't go into effect until 0500Z January 1, 1976, and are good until January 1, 1977.

CLASS-E CB DECISION DEFERRED again, will be reconsidered "later this year" as a result of March FCC meeting. Commissioners decided that Class-E CB issue could not be properly decided without taking both amateur and Class-D CB "re-structuring" dockets as well as the new automatic transmitter ID docket under consideration at the same time, and Reply Comments on the latest of these aren't due until July 16. Canada's objections to 220-MHz CB were also a factor.

COMMENTS ON DOCKET 20282 are arriving in a steady stream at the FCC, and several hundred have been received so far. Though no tabulation is being kept, most from Extras complain about loss of the exclusive phone bands and those from Generals and Techs bemoan their many losses. Very few flatly reject the proposal.

AMSAT EXPERIMENTER'S CONFERENCE in late March covered lots of ground, and tentative plans are for a "Phase 3" spacecraft on an elliptical orbit for launch in 1978. Like its predecessors, the new satellite would be a truly international project: design work is to be German, construction Canadian and ground support Australian.

Tech Class Licensees can use OSCAR 7, despite report to the contrary in east coast club paper — specific permission was a part of the FCC license issued to the satellite.

AMSAT Dues Will Double July 1 from $5 to $10 a year, so it would be wise to renew now for an extended period and save.

OSCAR 6 Telemetry supports the expectation that AMSAT's long lived "bird" will continue to be operational at least through next fall. Battery temperature, considered to be the most critical parameter, is dropping after the expected February peak.

6-METER BAND THREATENED by proposal to add another VHF TV channel. In its comments filed in response to Docket 20264, which pertains to radio call-box systems and their use in the 72-76 MHz band, a prominent Dallas consulting engineering firm has proposed that the public interest would be best served by moving channels 2, 3 and 4 down 2 MHz and putting a new TV channel, dedicated to non-commercial educational use, in the resulting 70-76 MHz band. Present users of the 72-76 MHz slot would move elsewhere, but the other 2 MHz would come right out of the amateur 50-54 MHz assignment!

Whether This Proposal will receive serious consideration by the Commissioners remains to be seen, but this threat — very similar to those of EMS on the high end of 420-450, HIRAN and 220-MHz Class-E CB, shows how others look at the present amateur assignments.
Since its introduction, the Yaesu FT-101B Transceiver has revolutionized amateur radio. Never before has so much quality, versatility and value been assembled in one compact package.

Here's the radio with just about everything amateurs have wanted: Power. Sensitivity. Reliability. Portability.

With 260 watts SSB PEP, plenty of punch on CW and AM, 0.3 μV receiving sensitivity, and 160 to 10 meters range. It's a great base station — that's ready to go portable when you are.

Because it's Yaesu — world leader in amateur radio — you know the FT-101B is backed by a solid warranty, a strong dealer network and convenient serviceability. The FT-101B Transceiver. The radio. From the radio company. See your dealer or write for our catalog. Yaesu Musen USA, Inc., 7625 E. Rosecrans, No. 29, Paramount, Calif. 90723.
large
vertical antenna

for 160 and 80 meters

A design approach for dealing with problems of erecting an efficient radiator to compete on the two lower bands

The decrease in sunspot activity has caused a renewed interest in low-frequency DX operation. On the 80- and 160-meter bands beams are impractical, and even dipoles must be unreasonably high to get the low-angle radiation necessary for DX. That leaves vertical antennas. Although omnidirectional, they are very good low-angle radiators. In theory, a short vertical radiates as well as a tall one; but in practice, the low radiation resistance of a short vertical, compared with ground and other resistances, makes its overall efficiency low.

My friend Liscum Diven, W71R, decided to erect a good-sized vertical hoping to increase his DX contest scores on 80 and 160. He is blessed with enough real estate to make this practical, considering the area required for guyng and a good ground system. While all amateurs are not so fortunate, the design procedures described in this article are applicable to more modest antennas — or larger ones.
height considerations

The first thing to be decided, of course, was the height. This factor is always a compromise between desired performance and cost. There is no good reason why a vertical, or any other antenna, has to be self resonant. An antenna will radiate all the power it can absorb. When an antenna is an odd multiple of a quarter-wavelength long the feed-point impedance is conveniently low for coax transmission lines, and the reactance is zero; but these are the only advantages to resonant antennas: they are easier to feed.

As for the vertical, the practical efficiency increases until a height of about 0.6 wavelength is reached. At greater heights the vertical radiation angle rises rapidly, making the antenna less desirable for DX.

Since W71R's antenna was to be used on both 80 and 160, the height could not exceed 0.6x80 meters, or 157 feet (48m). This was a little too high for W71R's tastes. Top-loading to reduce the physical height while maintaining the electrical height was considered but rejected because of mechanical difficulties.

It was finally decided to make the vertical 91 feet (28m) high, consisting of 70 feet (21m) of aluminum lattice tower sections, surmounted by a 21-foot (6.4m) whip that happened to be available. This configuration would make the electrical height of the antenna 0.347 wavelength on 80 and 0.166 wavelength on 160 meters.

It was decided to guy the antenna at two levels. The base insulator was to be a cluster of heavy-duty ceramic pillars. Since the dead weight of the antenna would be only about 100 pounds (37kg), and ceramic is very strong in compression, this type of base was quite practical.

The guys were to be 1/8 inch (3mm) diameter steel cable, with 6-foot (1.8m) sections of 1/2-inch (13mm) polypropylene rope to insulate the guys from the tower, and small egg insulators to break up the guys. The guy anchors would be 5-foot (1.5m) long earth augers.

Even if you are not particularly interested in erecting a vertical antenna, the following piece is well worth reading for a firm grasp on some of the physical aspects of all antennas. The part on characteristic impedance, which is treated in terms of an antenna as a transmission line, should help to dispel some of the misconceptions on antenna theory that we hear on the amateur bands. The graphs of resistance as a function of antenna height-to-diameter ratio, which were taken from reference 1, should provide a convenient design aid for those seriously contemplating the construction of a large vertical antenna. Editor
matching system characteristics

A lot of thought was given to the matching network. It was decided not to use the usual cut and try method; instead, the network would be engineered. The network was built before the antenna was erected, and required only minor adjustment when installed.

The following characteristics were desired in the network:

1. Obviously it must match the resistance and tune out the reactance. The antenna would be highly reactive on both bands since it would not be resonant on either.

2. It should use as few elements as possible and should be easily switched between bands.

3. It should have a permanent dc path to ground on both bands for lightning protection.

The design achieved all of these objectives.

First to be determined was, "what were we matching?" Any antenna is really a transmission line. Its termination is its own losses to space; but since this is a poor termination, the vswr is very high, as a graph of the voltage and current shows. As with all transmission lines, an antenna has a characteristic impedance. This is not the sending-end impedance. What is seen at the sending end is the antenna's losses to space, which are distributed along its length, transformed by the characteristics of the transmission line to a single resistance value called the base radiation resistance of the antenna. This resistance, when multiplied by the square of the current measured at that point, tells how much power is actually being radiated.

The characteristic impedance of the antenna is a function of the length-to-diameter ratio. A thin wire will have a characteristic impedance of 600 ohms or more; a lattice tower might have a characteristic impedance of 200 ohms or less. The lower the characteristic impedance, the less will be the impedance excursions with frequency at the sending end, which is true of all transmission lines. This means greater bandwidth.

The accurate calculation of the resistance and reactance of an antenna of irregular shape is impractical, but graphs are available that give fairly realistic...
values. These graphs, reproduced in figs. 1 and 2 and described in reference 1, were generated from vhf scale models and give resistance and reactance values for solid cylindrical antennas of different height-to-diameter ratios over a per-

fect ground, with the height of the antenna in electrical degrees as the parameter.

design assumptions

We didn’t know how a lattice tower of triangular cross-section related to a solid cylinder, but we guessed that it might be something like the diameter of a circle inscribed within the 11-inches (28cm) on-a-side triangular mast or 6 inches (15cm). We also thought that the top 21 feet (6.4m) of the antenna, which was a small-diameter whip, would reduce this dimension further. Since it was a nice number to work with, our final guesstimate was a height-to-diameter ratio of 200, which proved to be a good choice. Because W71R’s antenna would be 0.347 wavelength on 3.75 MHz, the electrical heights on those bands would be 59 and 125 degrees respectively.

The graphs, as closely as they could be read, yielded the following R and X values for the two bands:

<table>
<thead>
<tr>
<th>Frequency</th>
<th>Resistance, R (ohms)</th>
<th>Reactance, X (ohms)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.8 MHz</td>
<td>7</td>
<td>-160</td>
</tr>
<tr>
<td>3.75 MHz</td>
<td>180</td>
<td>+240</td>
</tr>
</tbody>
</table>

We further assumed that the ground system, fair but far from ideal, might represent a loss of 3 dB at 1.8 MHz. Adding 7 ohms, a loss resistance equal to the 1.8-MHz radiation resistance, might compensate for ground-system losses. The effective resistance values thus would be 14 and 187 ohms, respectively.

The antenna would require a series inductive reactance of 160 ohms to tune it to 1.8 MHz, but a shunt reactance was desired to provide a direct path to ground for lightning protection. So the series R and X from the graphs were translated to their equivalent parallel values:

\[
Q = \frac{X_p}{R_p}
\]

\[
R_p = R_s (Q^2 + 1)
\]

\[
X_p = \frac{R_p}{Q}
\]

This gave the following values:

<table>
<thead>
<tr>
<th>Frequency</th>
<th>Resistance, R (ohms)</th>
<th>Reactance, X (ohms)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.8 MHz</td>
<td>1820</td>
<td>-160</td>
</tr>
<tr>
<td>3.75 MHz</td>
<td>495</td>
<td>+386</td>
</tr>
</tbody>
</table>

Thus a shunt reactance of +160 ohms (14.1 μH) would tune the antenna. The parallel resistance value of 1820 ohms could most easily be matched by using
the loading coil as an autotransformer, connecting the 50-ohm transmission line to a tap on the coil. The fraction of coil turns across which the line should be connected was:

$$\sqrt{\frac{50}{1820}} = 0.166 = 16.6\%$$

neglecting leakage inductance. This took care of the 160-meter band.

A shunt capacitor would be required to tune the 80-meter band. This circuit would not furnish a direct path to ground, so it was decided to see what would happen if the 14.1-\mu H 160-meter loading coil were left in place on 80 meters. At 3.75 MHz this coil would present a reactance of +332 ohms. This reactance in parallel with the +386 ohms reactance of the antenna at 3.75 MHz gave a net reactance of +179 ohms, the resistance being unchanged. When this combination was translated back to series form, the reactance was \( R = 57.5 \) ohms and \( X = +159 \) ohms, a convenient value since it meant that on 80, with the 160-meter loading coil in place, the transmission line could be connected directly to the base of the antenna through a capacitive reactance of 159 ohms (267 pF) with negligible mismatch. The two-band matching network was thus very simple, consisting of a single inductor and a single capacitor with a spdt relay to switch bands. The network is shown in fig. 3.

W71R works both phone and CW on 80, so the bandwidth was calculated by obtaining resistance and reactance values for the antenna and network components at 3.5 MHz and 4 MHz and plotting the results on a Smith chart. This data showed that the vswr would be less than 2:1 over the entire band.

**construction and tuneup**

The network was built into an old breadbox; components were from an old rig. The coil had a Q of over 200 on both bands, so its loss was negligible. The antenna was erected without mishap. A sign-erection truck was hired for the occasion, and a few local hams held guy wires.*

The radials were put in with the aid of a *mole*, which is a tool about the size of a power lawnmower designed for digging shallow trenches for the pipes of underground sprinkler systems. Sixteen

---

*Also try your local phone company or a tree-trimming service. They have mobile cherry pickers with operators that can often be hired for a fairly reasonable fee. Editor
radials about 125 feet (38m) long were installed. More radials would have been desirable and probably will be installed later. But it was only a week before the start of the DX contest, and even with the mole it was hard work. Then came the tune up. Would the network act as predicted? It had already been built.

Author W71V supporting W71R's antenna. Concrete base is 18 inches (45.7cm) by 1 foot (30.5cm). Tuning network and ceramic insulators are shown.

It was our intention first to measure the resistance and reactance of the antenna, as a check on the curves and to get an approximation of the actual ground resistance. This would be done by subtracting the 7 ohms radiation resistance at 1.8 MHz taken from the graph from the measured total value. This turned out to be impossible for an unforeseen reason. A local broadcast station produced a signal of 20 volts at the base of the antenna, making use of an rf bridge impossible. The BC station would not shut down for us so the network was tuned, first on 160, by energizing the network and antenna with enough transmitter power to overcome the BC signal, then adjusting the inductance for maximum voltage across the coil as read by an rf vtvm. Then the transmission line tap on the coil was selected for minimum vswr. Next, power at 3.75 MHz was fed to the network, and the series capacitor adjusted to null the vswr.

The final values came out extremely close to the calculated values. The 160-meter loading coil turned out to be 14 $\mu$H (right on the nose) and the 80-meter series capacitor was 320 pF rather than the 267 pF calculated. The transmission line tap on the coil was at 24% rather than 17% of the turns.

Curves of vswr versus frequency are shown in fig. 4. The bandwidth is somewhat greater than calculated. This is not necessarily good, however, since it probably means that the ground losses are higher than assumed.

**conclusion**

As this is being written, the DX contest has just ended. Contest scores, of course, are highly dependent on conditions and the number of stations and countries participating. But W71R reports that the overall performance on both bands was far superior to that of the high inverted-vees previously used.

On 160, although activity was sparse and noise levels high, W71R worked every DX station he heard. On 80, W71R felt that, for the first time, he had an antenna that really put him in a good competitive position. The antenna gave him the feeling that he was really getting through - every serious DXer knows that's what really counts.

*ham radio*
graphical design
method for
log-periodic antennas

A no-math approach
to the log periodic
design problem

Anyone who has designed or studied log-periodic antennas is aware of the math involved due to the many variables that enter into the design problem. References 1-5 contain several pages of formulas and refer the reader to four or five nomographs, log tables, etc. Probably this is one of the reasons the log-periodic antenna has been neglected by the amateur fraternity. Furthermore, little information has been published on the design of hf L-P antennas in amateur publications.

When I retired in 1970 I decided to make a study of high-frequency log-periodic antennas. The original antenna in use here has only 7 elements, is limited to 20 and 15 meters, is less than 40 feet (12.2m) long, and is pointed south. Over the past three years it has averaged 8-10 dB gain compared with a 20-meter dipole at the same height. The results obtained from this beam prompted a second, larger log-periodic for 20, 10 and 15 meters having a boom length of 70 feet (21.3m). Three log-periodics were erected and tested during 1970, and as of this writing 17 have been put up and tested.

This article presents a graphic design approach for log-periodic antennas that eliminates the work associated with the math involved. Four designs are presented first, each having essentially the same boom length and apex angle, but with different numbers of elements. Each should provide approximately 10-dB gain referenced to a dipole at the same location and height above ground.

Additionally, two more log-periodic designs are shown, one with a 54 foot (16.5m) boom that gives about 8-dB forward gain and one with a 100-foot (30.5m) boom. (Both boom lengths are nominal.) This last design is presented for those with enough real estate to accommodate it and the nerve to hang such a monster in the air. It will give 12-dB forward gain (referenced to a dipole) if properly designed and assembled and suspended at least 40 feet (12.2m) above ground. All designs cover 14 to 30 MHz.

the log-periodic antenna

For those readers not acquainted with the log periodic, it is a broadband multi-element, unidirectional, end-fire array capable of 8- to 14-dB forward gain. The front-to-back ratio is usually 10 to 14 dB with side attenuation to about 25 dB. The forward lobe of the
log-periodics tested here generally runs about 90 degrees in the H plane. Its vertical angle of radiation, or take-off angle, can be controlled fairly well by height above ground. The swr at the feedpoint remains relatively constant over the frequency range for which the antenna is designed, generally not exceeding 2:1 with 1.5:1 as typical; usually varying between 1.1:1 and 1.5:1.

A bandwidth of 10:1 is normal for fixed commercial log-periodics designed to cover frequencies between 3 to 30 MHz; however, they are quite long, usually 250-800 feet (76-244m), depending on gain required and beamwidth. Some of the commercial log-periodics having a limited bandwidth of 4-30 MHz are 150-350 feet (46-91m) long, and for 6-30 MHz, 100-250 feet (30-76m) long. The commercial rotary types generally have a boom length of 40 to 74 feet (12-22.5m). Some of these are used at MARS stations.

For amateur applications, a fixed log-periodic wire beam can be limited to a bandwidth slightly more than 2:1, covering 7-14.5 MHz for 40 and 20 meters or 14-30 MHz for 20, 15 and 10 meters without being excessively long. By limiting bandwidth still more, say 14 to 22 MHz, a log-periodic can be trapezoidal type, one the sawtooth structure and the other the zig-zag, have been tested on 20 meters. Some of these log-periodic antennas have been described in amateur publications6-10 with complete dimensions and assembly details.

In addition, several special log-periodics have been designed on paper covering other frequencies. Some covered both MARS and amateur bands; several were for special vhf and uhf TV channels; and, I blush to say, one covered 26-27 MHz for a CBer wanting a good skip antenna.

After designing my first three log-periodics the hard way with the formulas, I felt there must be an easier design method. When designing the
original antennas, I always made an assembly sketch on graph paper after arriving at the correct element lengths and spacing distances. Since the outline of a log-periodic results in an isosceles triangle, with the long rear element being the base and the shorter forward elements forming the triangle toward the apex, the following simple no-math graphic design method became apparent. I believe this simple design method will be of interest to any amateur wishing to design a log-periodic for a particular band, bandwidth, or to fit a log-periodic into a given space.

graphic design method

You will need the following materials: graph paper, 1/10 cross section, 8½x10½ inch (21.5x26.7 cm) or larger; an architect or engineer's scale; a protractor; and some French curves (not absolutely necessary but helpful in designing the side catenary lines).

For the first example we will design an L-P for 20, 15 and 10 meters or for operation on any frequency between 14 and 30 MHz.

1. First determine the low- and high-frequency cutoff required or frequencies over which the L-P is to operate, or its bandwidth.

2. Next determine the amount of space available when the L-P is aimed in the desired direction. If there is a space limitation, it may be necessary to reduce the boom length, losing some gain. This is discussed later.

3. Determine the length of the longest (rear) element and the shortest (forward) element:

Rear element. The rear element should be at least 5% longer than the lowest cutoff or operating frequency. Using the usual formulas:

\[
\frac{1}{2} \text{ wavelength} = \frac{468}{\text{MHz}} = \frac{468}{14} = 33.4 \text{ feet (10.2m)}
\]

\[
33.4 + 5\% = 34.4 + 1.7 = 36 \text{ feet (10.9m)}
\]

Since a slightly longer length is better, we will use 36 feet (10.9m) for the rear
element. This element length will resonate at \(468/36 = 13.0\) MHz.

**Forward element.** The shortest element should resonate 45 to 50% higher in frequency than the desired high-frequency cutoff. From my experience, the swr will be lower by using a high-frequency cutoff plus at least 50%:

\[
30 \text{MHz} + 50\% = 45 \text{MHz}
\]

\(\frac{1}{2}\) wavelength at 45 MHz = 468/45 = 10.4 feet (3.2m)

We now have the required length of the rear element, 36 feet (10.9m) and the forward element, 10.4 feet (3.2m)

4. We will now estimate a boom target length to determine a practical distance from the long rear element (E1) to the short forward element. From experience, an L-P designed to cover an octave (2:1 bandwidth) should have a boom length from 1.5 to 3 times the length of the rear element. If the boom length is less than 1.5 times the rear-element length, the apex angle will exceed 40 degrees and the forward gain will suffer. In other words, the gain drops off quite rapidly for a boom length less than \(E1 \times 1.5\), or with an apex angle of more than 40 degrees.

From the L-P formulas and nomographs in the references it will be noted that the \(\alpha\) angle (which is \(1/2\) the apex angle); relative spacing, \(\sigma\); design or scale factor, \(\tau\); and other variables all govern the forward gain, front-to-back ratio, etc. The design factor, \(\tau\), given by references 4 and 5, is of special interest because it gives gain figures between 7.5 to 12 dB for various combinations of these formulas. However, the purpose of this article is to eliminate all formulas, so the information above is for those wishing to pursue further study.

We now have sufficient dimensions to start drawing the graphic L-P. In laying out the first antenna, use a scale of 10:1. Referring to fig. 1, proceed as follows:

5. First draw the longitudinal center line, X-Y. Now draw the longest element, E1, (line A-B) determined by step 3 to be 36 feet (10.9m).

6. A boom length of \(2 \times E1\) will be used for the first example; \(36 \times 2 = 72\) feet (21.6m). We will use 70 feet (21m)

---

**Fig. 3. An L-P with 14 elements and a 70-foot (21.3m) boom.**
as the target length and try not to exceed this length.

It will be found later that this overall length may vary plus or minus a few feet, but we will try not to exceed an overall length of 70 feet (21m). This will also give us a target length for fore and aft mast spacing.

Now measure 70 feet (21m) along the X-Y centerline from point X (or the rear element) toward Y, making a dot at exactly 70 feet (21m), which will be called Y'.

8. Draw line A-C and extend it until it crosses the X-Y axis. Next draw line B-D, extending it to also cross X-Y. If all drawings to this point have been accurate, these lines will meet, forming the apex, (Y), of an isosceles triangle, A-Y-B.

9. The next step is to add the remaining elements between the rear element, E1, (line A-B) and the short, forward, target element, which should fall near the temporary element (line C-D).

Precise measurements must be made for the remainder of this design. For this reason an accurate scale must be used and the lengths should be read or estimated to 0.1 foot (3cm). Fig. 2 will now be used to complete the L-P. Our next objective will be to determine a correct spacing ratio between the elements.

**Element Spacing**

Since a log-periodic antenna can be considered a unidirectional, end-fire array having a series of driven elements, a spacing distance of 0.05 to 0.2 wavelength should provide the best gain, as
the two adjacent elements are out of phase because of transposition between elements, which is required for a log-periodic antenna.

For starters we’ll use an element spacing of approximately one-tenth wavelength between elements such as the rear (longest) element, E1, and the following element, E2; and between E2 and E3, etc. An easy method of approaching this spacing is to divide the rear-element length by 5: 36/5 = 7.2 feet (2.2m). For this simple design method, this might be considered similar to the “relative spacing ratio, \( \sigma = dN/21n \),” or “the mean spacing factor, \( \sigma' = dn/21n \),” or “design ratio, \( r = 1n/L1-1 \),” in the log-periodic design formulas, which can be obtained from references 1-5 and 11. We shall, however, proceed with our no-math design method.

10. Refer to fig. 2 and accurately measure 7.2 feet (2.2m) from the center of element E1 (point X) down X-Y and mark the position with a dot. This point will be the location of the second element, E2. Now draw E2 and measure its exact length between the sides of the triangle. As shown by fig. 2 this length will be 33.4 feet (10.2m). (The remaining elements and element spacing will be referred to as E3...En and S2...Sn, respectively.)

11. Next determine the second spacing distance, S2: E2/S = 32.5/5 = 6.5 feet (2.0m). Mark this distance, S2, draw E3, and measure its length, which will be 31.0 feet (9.4m).

12. Continue the mark-draw-measure-divide procedure, very accurately, to obtain the remaining spacing distances and element lengths until the last and shortest element is reached, which should be close to 10.4-feet (3.2-m) long and should be approximately ±1 foot (30cm) from our boom target length, depending on how accurately the measurements have been made and drawn. We now have all element lengths and spacing distances for a 17-element log-periodic for 14-30 MHz having a boom length of approximately 69 feet (21m). As measured by the protractor, the apex angle is approximately 20 degrees. Considering this angle, number of elements, and the boom length, this
L-P should give a forward gain of approximately 10 dB if the antenna is one-half wavelength above ground, or at least 35 feet (10.7m) on 20 meters.

Although 17 elements are good from an swr standpoint, a smaller number of elements can be used, as mentioned later. Twelve to 13 elements are generally the minimum required for an L-P designed to cover an octave. Using less than 17 elements will reduce weight, cost and labor.

a 14-element design

Fig. 3 illustrates a similar 14-30 MHz L-P also using a 70-foot (21.3m) boom target length but instead of the ratio L(E)/5, a ratio of L(E)/4 is used, resulting in 14 elements. Note that the boom length is almost exactly 70 feet (21.3m) and the apex angle remains the same as the 17-element L-P, fig. 2.

11- and 13-element designs

Fig. 4 is an equivalent L-P but the ratio L(E)/3 is used, resulting in only 11 elements. As 12 to 13 elements are a minimum for a 2:1 bandwidth, fig. 5 is generated using a ratio L(E)/3.8, which gives 13 elements. This should be the optimum of the four L-Ps all having approximately the same final boom length and apex angle.

Any one of these designs would have about equal forward gain; however, the 11-element design would probably not have as smooth or flat an swr across its bandwidth due to a minimum number of elements vs bandwidth. The swr might exceed 2:1 on some frequencies.

The 13-element array is one of the L-Ps assembled and being used here. Note that an odd number of elements is suggested from a mechanical assembly standpoint, as explained in some of my previous articles.

From the four L-Ps illustrated in fig. 2, 3, 4 and 5, it will be noted that the elements vary as follows: 11 for L(E)/3, 13 for L(E)/3.8, 14 for L(E)/4, and 17...
for $L(E)/5$, each having essentially the same boom length and apex angle. Each should give approximately 10 dB gain.

14-30 MHz log-periodic with minimum boom length

If space is not available for a 70-foot (21.3m) boom length, the minimum length of 54 feet (16.5m) ($E_1 \times 1.5$) can be assembled per fig. 6. The ratio of $L(E)/5$ is used, which gives 13 elements. Since this antenna has a length only 1.5 times that of the rear element (or approximately 3/4 wavelength boom length), and the apex angle is 36 degrees, its gain will probably not exceed 8 dB.

14-30 MHz L-P with 100 foot (30.5m) boom length

For those desiring maximum gain from an L-P for 20, 15 and 10 meters and if space is available, the 14-30 MHz L-P boom length can be extended to approximately 100 feet (30.5m) as illustrated by fig. 7 which, if properly assembled and suspended at least 40 feet (12.2m) above ground, will give a gain of 12 dB.

$L(E)/3.3$ was used for generating this L-P. The boom target length was 100 feet (30.5m). For this drawing the last element, $E_{17}$, is 101 feet (30.82m) from the rear element starting point, which overshot our target by 1.1 foot (34cm). Sixteen elements could be used, which would be 98.0 feet (29.9m), but as mentioned previously, an odd number of elements is desirable from a mechanical standpoint; therefore, the extra 1.1 feet (34cm) should be acceptable.

Thirteen elements are suggested for the shorter 50- and 70-foot (15.2 and 21.3m) L-Ps and 17 elements for the 100-foot (30.5m) length. I have tried all three configurations. A 70-foot (21.3m) L-P is used for my northeast beam and the 100-foot (30.5m), 17-element array for the beam directed west, which has given outstanding performance.

Since the 10-meter band may not be of interest now due to propagation conditions, this portion of the L-P designs can be eliminated by deleting elements shorter than 15 feet (4.6m); i.e., for the 13 element L-P, fig. 5, elements 10, 11, 12 and 13 can be deleted, reducing the length by 14.3 feet (4.4m) leaving a 9-element L-P covering 14-21.5 MHz for 20 and 15 meters.

For the shortest L-P, fig. 6, deleting the four forward elements would reduce the length by 10.9 feet (3.3m) or a boom length of 41.2 feet (12.6m). This 20- and 15-meter beam could then be erected in a space 40 x 45 feet (12.2x13.7m). Likewise, for the 100-foot (30.5m) L-P, fig. 7, elements 12, 13, 14, 15, 16 and 17 can be deleted, reducing its length 23 feet (7m), leaving an 11-element L-P with boom length of 78.2 feet (23.9m). The deletion of the 10-meter section of these L-Ps will have little effect on the gain on 20 and 15 meters, since the apex angle is unchanged.

40- and 20-meter log-periodics

The same graphic approach can be used for designing an L-P covering 7-14.5 MHz for operation on 40 and 20 meters; however, by doubling the element lengths, spacing distances, and boom length of the 20-, 15- and 10-
meter L-Ps (fig. 2 through 7), 40- and 20-meter L-Ps can be assembled, except possibly that of fig. 7, since it would be over 200 feet (61m) long. The L-Ps of fig. 2, 3, 4 or 5 would become 140 feet (42.7m) long; however, the shortest L-P, (fig. 6), would be only 108 feet (32.9m) long.

By adding four or five short forward elements and extending the boom length slightly, a 40- and 20-meter L-P can be modified to cover 7 to 21.5 MHz for operation on 40, 20 and 15 meters, which are probably the most-used bands at present. A 40-, 20- and 15-meter L-P was described in reference 7, which was of the skip-band type having a portion deleted between 7 and 14 MHz. An L-P for 40 meters should be at least 70 feet (21.3m) high for DX work.

For those wishing to design an L-P covering a bandwidth greater than a single octave, 12 to 13 elements are about the minimum that should be used. Additional elements can be used as the boom length is increased. For a 3:1 bandwidth, no less than 18 or 19 elements will be required; for 4:1 approximately 21 will be required.

In reference 7 a single-band L-P for 40 meters was described which has been tested here. Single-band L-Ps can be assembled for any of the high-frequency bands using the graphic design method. Five elements are sufficient and the swr remains relatively flat across the band for which the antenna is designed. A total of five different single-band L-Ps have been tested here on several bands. With an apex angle of 32 -

![Figure 7](image)

**fig. 7. Big Daddy — an L-P with 17 elements and a boom length of 101.1 feet (30.8m). Gain is approximately 12 dB.**

36 degrees, the single-band L-P will generally show a gain of 8 to 10 dB provided it is suspended approximately one-half wavelength above ground.

**vertical monopole log-periodic antennas**

The vertical monopole L-Ps for 40 and 80 described in reference 9 were also assembled by the graphic design method. The ratio L(E)/5 is best for a single-band, 5-element dipole or monopole L-P since element E2 will be spaced approximately one-quarter wavelength from the shortest element; and the open-wire center feeder, which is one-quarter wavelength from the feedpoint to E2, or the active element, also serves

22 May 1975
as an impedance-matching transformer between element E2 and the higher impedance at the feedpoint, which is of the order of 200 - 300 ohms. Thus a 4:1 balun can be used.\(^{12}\)

**summary**

Of the nearly twenty different log-periodic antennas I have built and tested, all but the first three (erected in 1970) have been designed by the graphic method. Although this simple procedure may seem crude, and may not be as accurate as an L-P designed entirely by the formulas, all antennas have produced the same results. In addition to the dipole log periodics, I have erected and tested three of the monopole L-Ps, which have quarter-wavelength vertical radiators and ground radials. These were tested on 40 and 80 meters. My graphic design method has also been applied to two of the trapezoidal sawtooth and zig-zag log-periodic designs now being tested on 20 and 15 meters.

I hope the simple non-math graphic design method will be of help to those wanting a special L-P for a particular frequency range or to fit in a limited space. To obtain maximum gain, make the L-P as long as possible for the given space; this will in turn give a minimum apex angle. Also use a sufficient number of elements to keep the swr relatively flat across the band for which the antenna is designed.

If you plan an L-P for 20, 15 and 10 meters, try to make the boom at least 54 feet (16.5m) long and use a minimum of 13 elements. If you are not interested in the 10-meter band, it would be better to design the L-P to cover 14 to 22 MHz only for 20 and 15 meters, using the 54-foot (16.5-m) boom length for a 9-element 14 to 22 MHz L-P. This would reduce the apex angle to 32 degrees and the gain would be approximately 10 dB vs 8 dB for the 20-, 15- and 10-meter antenna on the same boom length.

**acknowledgements**

I wish to thank the many amateurs who have assisted in on-the-air tests of these L-Ps for the past four years and for the many letters, phone calls, visits and QSOs by those interested in L-P design. I particularly thank those who have actually erected and are now using L-Ps similar to mine described in the references.

Design and construction of a four-element phased array for 40 meters that provides nearly 9 dB forward gain

For the last ten years, during the Antarctic winter, I have been handling phone-patch traffic from KC4-land on 40 meters. At this end I have been using a pair of phased verticals. In Antarctica they have used log periodics, vees, rhombics and monopoles. I usually receive good signal reports, but their signals are often buried in summer static and difficult to copy.

I have often tried to get the operators in Antarctica to try phased vertical antennas, but they change crews every year, and no one was apparently very interested. Then, three years ago, I began working Byrd Station nearly every night with Bob Conner, and I told him that I thought a set of phased vertical antennas would solve their problem.

When he came back for two-years stateside duty we got together and planned that when he went back to Antarctica in 1974 we would try out the idea. I outlined the plan for the vertical array, and we discussed it thoroughly, planning to ship everything to Antarctica, down to the last solder lug.
The Navy bought four trapped vertical antennas, Hy-Gain 14AVQs, and Bob got the necessary wire and fasteners to mount them. The logistics turned out to be a real cliff hanger with the antennas barely making it on board the last plane into McMurdo Station. It was a great deal of work in the icy weather, but finally, on February 9th, 1974, one vertical was installed. Bob was pretty discouraged, though, because the single vertical picked up so much noise from the big, nearby Navy installation that it was unusable. I told him to be patient and put up another one a half-wavelength away and hook them up as a broadside array. On February 11th the signals from McMurdo came through loud and clear, and Bob said that the interference had dropped almost to zero.

When the four vertical antennas were installed at McMurdo Station, their 40-meter signals began coming in about 0700 GMT at 10 to 40 dB over S9. Everyone there (and here) was ecstatic, and stations all over the states began breaking-in to tell the KC4USV operators their signals had never been so loud. Note that this was before the 40-meter season normally opened. We did not expect to use 40 meters except for tests, and had planned to meet on 20 meters for coordination. We did not expect 40 to be usable until sometime in April.

The broadside array with half-wavelength spacing has very broad nulls on the side and a narrow 60° beam which takes out noise on either side quite well (fig. 1A). The forward gain is about 3.86 dB. Quarter-wavelength spacing of the verticals results in a cardioid pattern (fig. 1B); the beam width is about 120° and the only good null is toward the rear. However, this pattern has a lower forward angle of radiation, and is best for extreme distances. Forward gain is about 4.5 dB.

Combining the half-wavelength spaced broadside array with the quarter-wavelength spaced system (fig. 2) provides nearly 9 dB forward gain. This is better than a three-element beam and at a lower angle unless you have a real man-sized tower. The pattern is similar to that of a Yagi (fig. 1C).

Construction

A plan view of the four-element phased array is shown in fig. 3. The phasing lines between the quarter-wavelength spaced elements (A-D and B-C) are 3/4-wavelength long because,
when the velocity factor of the RG-8/U coaxial cable (0.66) is taken into consideration, a quarter-wavelength coaxial line is too short to reach between the elements. The 3/4-wavelength phasing line provides the same phase delay.

![Diagram](image)

**fig. 2.** The four-element 40-meter phased array used at KC4USV uses four Hy-Gain 14AVQ trapped verticals.

Although a tee connector is shown between the two half-wavelength spaced elements (A and B), in the installation at McMurdo Station the tee connector is actually located inside the station. Because of the severe weather conditions during the winter, and frequent 100 mph (160 kmh) winds, this system allows either quarter-wave spaced pair to be used separately in case one of the verticals of the other pair is brought down or damaged by the wind.

It would also be possible to feed antennas C and D with one feedline, and antennas A and B with another, placing the phasing line inside the shack. With this system the pattern of the array could be reversed.

The antennas at McMurdo Station are mounted on a hill of volcanic ash and the electrical ground is down about 30 feet (9m). It was originally planned to use ground radial mounting, but the volcanic ash has extremely low conductivity, and the antennas are mounted on about six feet (1.8m) of pipe, so they are located a quarter wavelength above electrical ground. This is ideal for a ground plane. One radial was installed on the far side and five radials on the near side to support the antennas and provide the best ground plane toward the desired direction (see **fig. 3**). The radials are each insulated at the outer, high-voltage ends.

**performance**

Because of poor performance in previous years, in 1974 the Navy installed a Collins log-periodic on a 100-foot (30.5m) tower. We tested the phased array twice against the big log-periodic, once under good conditions, and once under the poorest conditions. The log-periodic had less than 3 dB advantage over the phased vertical array. The old 40-meter beam, used for years, sounds pitiful by comparison.

![Diagram](image)

**fig. 3.** Dimensions of the 40-meter phased array. Gain of this antenna is nearly 9 dB.

An unexpected bonus made the phased array even more valuable. Since the four verticals are trapped designs for operation on 40, 20, 15 and 10 meters, performance on 20 meters is good.
dropping one cardioid section, the remaining section becomes a half-wavelength end-fire array on 20 (it also works well on 15 meters). Trapped antennas were originally chosen because they were shorter, and less likely to be installed temporarily as a half-wavelength spaced broadside pair so contact was resumed in a few days. When the ham shack was rebuilt the four-element phased array was placed back in operation. The big log-periodic on the 100-

The phased array at KC4USV is mounted approximately 6 feet (1.8m) off the ground on a sloping hillside so the rear pair of antennas is about 7 feet (2.1m) higher than the forward pair. This results in an extremely low vertical radiation angle. Standing by one of the antennas is Bob Conner, WB2BCJ, who installed the array at McMurdo Station in Antarctica.

blown down in high winds, so multi-band operation of the array was an added bonus.

postscript

On July 22nd, 1974, an ice storm hit McMurdo Sound with winds to 138 mph (222 kmh), tearing off the roof and one wall of the ham shack. The storm also took out the large elements of the big log periodic, making it unusable on 40 meters. The four 14AVQ verticals in the array, however, were completely undamaged.

All the amateur radio gear was moved to another building and two spare 14AVQ vertical antennas were installed temporarily as a half-wavelength spaced broadside pair so contact was resumed in a few days. When the ham shack was rebuilt the four-element phased array was placed back in operation. The big log-periodic on the 100-

foot tower, on the other hand, had to wait until summer.

As a sidelight, to show what the weather is like at McMurdo Station, on August 8th a plane came in from Christ Church, New Zealand, 2000 miles away, air dropped nine sacks of mail, weighted with sand, from about 400 feet (122m) and returned non-stop to New Zealand. One bag broke open and three others were carried away by the wind. Two of the three bags were found 20 miles (32km) away and one was finally recovered 45 miles (72km) away. The mail from the broken bag was only partially recovered!

Ham radio
It's not necessary to use solid or screened reflector surfaces — properly spaced reflector elements provide the same performance.

The subject of parabolic reflector element spacing is like the weather — nearly everybody talks about it, but few people do anything about it. One reason is that there are a large number of parameters relating to good parabolic antenna design, and the matter of reflector element spacing seems to have been lost in the shuffle.*

It is possible to avoid the issue of reflector spacing by adding metal screening or using a solid metal surface as many builders have done.¹² Some of these designs however, take special skills and the cost is likely to be high. As an alternative, an all-metal dish can be purchased on the surplus market.

*Sometime after preparing the material for this article, author WA9HUV discussed it with Edward F. Harris, Chief Engineer with Mark Antennas, and discovered that Harris had done similar work in the 1950s. His report, "Designing Open-Grid Parabolic Antennas," appeared in the November, 1956, issue of Electronic Industries magazine.
On the other hand, several low cost parabolic-reflector designs employing aluminum tubing have appeared in amateur radio magazines in recent years. The question is, are these designs really inferior to solid reflector designs, and if so, to what extent? What are the performance compromises one is willing to make when consideration is given to cost, mechanical strength and stability, portability, ease of construction, mounting, wind-loading and weight?

It seems reasonable to assume that if the elements of a reflecting screen are located extremely close together in terms of operating wavelength, then most of the incident energy will be reflected and very little will be transmitted through the screen. On the other hand, if the reflector elements are many wavelengths apart, it seems clear that a large portion of the incident energy should pass through uninhibited. By intuition, it does not seem likely that a screen of reflectors suddenly becomes completely reflective at some critical value of element spacing. It also follows that the screen probably does not become completely transparent when this critical value of element spacing is slightly exceeded. Just how does the reflective property vary with element spacing?

In an attempt to answer these questions I performed a series of experiments. The results, which are the subject matter for the balance of this article, should be of interest to future builders of parabolic reflectors.

test setup

To perform the experiments, a wooden frame 20-inches (51-cm) wide was made of furring strips. Holes were drilled in the sides of the frame 3/4-inch (19-mm) apart so that 24-inch (61-cm) long aluminum tubes, 7/16-inch (11-mm) OD, could be inserted and stacked like a venetian blind, with the elements separated by 3/4 inch or any multiple of 3/4 inch. A sketch of the frame is presented in fig. 1.

Two kinds of experiments were performed, one to test the transmission and the other the reflective properties of the screen as element spacing was varied. A battery-operated 2304-MHz small-signal source driving a circular horn antenna was used as the transmitter.

A similar horn antenna was used to feed a 2304-MHz converter. The 2304-MHz test frequency was chosen so that the reflecting screen could be kept reasonably small. If the experiment were performed at 432 MHz, for example, much longer reflector elements and a physically larger frame would have been required.

In the second set of experiments both the receiving and transmitting horn antennas were located on the same side of the reflector, side-by-side, and oriented so that maximum reflected signal was received. When the reflector was removed, the crosstalk between horns was too small to operate the S-meter in my receiver. The elements of the screen were then added in various combina-

---

fig. 1. Sketch of wooden frame used to vary the space between reflector elements. Test setups are shown in fig. 2 and 3.

May 1975
tions of spacing, and the S-meter reading recorded for each case.

**Test Results**

In the first set of experiments in which the receiving and transmitting antennas were separated by the screen, very little signal reached the receiving antenna for element spacings up to 1½ inches (38mm). At 2¼ inch (57mm) spacing, the screen became slightly opaque, while at 4 inches (102mm) it was almost completely transparent. It is interesting that for the 3-inch (76 mm) spacing, approximately half of the incident energy was transmitted through the screen. Fig. 2 shows the results of these tests.

Fig. 3 shows the results of the second set of tests. With spacings up to 2½ inches (57mm), most of the transmitted signal power was reflected into the receiving horn. With 3-inch (76mm) spacing, half the power was reflected and half was transmitted through the screen. This correlates very well with the first set of experiments. For spacings of 3-3/4 inch (95mm) or more, nearly all of the incident energy passed through the screen.

**Data Analysis**

The data shows clearly that the screen is a good reflector for element spacings less than 3 inches (76mm) at 2304 MHz, and a poor reflector for spacings greater than 3 inches (76mm). The space between the 7/16-inch (11mm) OD aluminum tubes for a 3-inch (76mm) center-to-center spacing is 2.5625 inches (65mm). Recognize that a free-space half-wavelength at 2304 MHz is very nearly the same value, or 2.563 inches. Further thought suggests that the adjacent elements may operate on much the same principle as a transverse magnetic (TM) mode waveguide. To test this idea, note that the cutoff frequency in such a case depends on the dimensions of the waveguide in the following manner:

\[ \lambda_c = \frac{2ab}{\sqrt{a^2 + b^2}} \]
This equation can be illustrated geometrically as shown in fig. 4. Note that as the $a$ dimension is increased to infinity, which is the case of parallel reflector elements, then $\lambda c/2$ approaches $b$. This is exactly the result that the experiments led to. In other words, by definition, the cutoff frequency of a curtain of parallel reflector elements occurs when the space between adjacent elements is one-half wavelength.

This interesting result also implies that the diameter of the reflectors has little to do with the cutoff frequency, since it is the open space between the reflector elements that is significant. Therefore, the analysis also applies to tubes of different diameters as well as to reflector elements having different cross-sectional shapes.

The experiments also show that at the cutoff spacing, the loss in terms of percentage of power transmitted is 3 dB. This can be interpreted to indicate that the illumination efficiency of a parabolic reflector with element spacing corresponding to the cutoff frequency would be 50%. For example, assume a dish diameter of 12 feet (3.7 meters) operating at 2304 MHz; its gain, if it was well designed in all respects, is given by

$$\text{Gain} = 0.59 \left( \frac{\pi D}{\lambda} \right)^2 = 0.59 \left( \frac{\pi 3.7}{0.13} \right)^2 = 4703 \text{ or } 36.7 \text{ dB}$$

where $D$ is the diameter of the reflector, $\lambda$ is the operating wavelength and the coefficient 0.59 accounts for the illumination efficiency of a well designed dish. If the element spacing was the critical value, however, allowing half the incident power to pass through the elements, the dish gain would be 3 dB less, or 33.6 dB. The overall efficiency of such a dish would be 29% instead of 59%.

It is interesting to note that, even with losses of this magnitude, the ERP of this dish would be over 10 kW when fed with 5 watts. If the element spacing was reduced to 2 inches (51mm) however, the ERP would increase to over 20 kW at 2304 MHz.

**Economical 432-MHz Design**

On the basis of these experimental and analytical results, a parabolic reflector can be built for 432 MHz having only 1 dB reflector loss if the elements are spaced 12 inches (30.5cm) apart. In this case, only 13 reflector elements are needed for a 12-foot (3.7-meter) dish.

The design would be very lightweight and would have relatively low windcross section. Compared to the ideal dish made of solid sheet metal, this dish would have an illumination efficiency of 47% instead of 59%, and a gain of 21 dB instead of 22 dB.

**1296-MHz Dish Design**

It is interesting that 7-foot (2.1-meter) parabolic receiving antennas manufactured for TV use employ 4-inch (10.2 cm) spacing. This makes them useful at 1296 MHz without the addition of hardware cloth or other metal screening if you are willing to accept approximately 1.0 dB reduction in gain compared to a solid metal design. The gain of such a dish is 26 dB at 1296 MHz. If the loss of a dB makes you nervous, the dish diameter can be increased by 12% to compensate for the loss. Thus, a 12-foot (3.6-meter) dish should be made 13 feet (3.96 meters) in diameter, while...
the 7-foot (2.1-meter) dish diameter should be increased to nearly 8 feet (2.4 meters) to compensate for 1 dB of reflector transmission loss.

It should be recognized that the parallel element dish is sensitive to polarization and will not work well with dual or circularly polarized feed systems such as may be desirable for EME or satellite communications. However, it is entirely feasible to use a second set of reflectors at right-angles to those already described to eliminate polarization sensitivity. Such a dish, if designed for 432 MHz, for example, would have a surface resembling a 12x12-inch (30x30cm) mesh if made of 7/16 inch (11 mm) diameter aluminum tubing.

### on the air tests

The 12-foot (3.6-meter) parabolic reflector I use was put into service in 1970. Initially, it was not covered with screening. Tests performed before and after adding expanded aluminum screening both on 432 MHz and 1296 MHz did not indicate any difference in performance or gain.

More recently, comparative tests were run with and without screening on 2304 MHz, and a small reduction in gain was noticed. The radiation patterns on

### fig. 5. Azimuth patterns of WASHUV’s 12-foot (3.6-meter) parabolic reflector at 432, 1296 and 2304 MHz (photograph of dish is shown at beginning of article).
all three bands did not change however. Fig. 5 shows the patterns of the 12-foot dish without screening for 432, 1296 and 2304 MHz. These patterns were taken with the aid of battery-operated signal sources located approximately 0.2 mile (0.32 km) from the dish, and elevated above ground to the same height as the center of the dish. The pattern test conditions were fairly ideal since the line of sight path was unobstructed, giving essentially free-space conditions.

**summary**

Probably the most simple and effective parabolic reflector design is the one described in this article. The reflecting elements should be oriented parallel to the direction of polarization of the exciting wave. Thus, for horizontal polarization which is in most general use for amateur purposes, the elements of the parabola should be oriented horizontally. The space between elements should be less than a half wavelength at the highest operating frequency. To reduce the loss through the reflector to 1.0 dB, the space between reflectors should be approximately 0.439λ. Table 1 shows center-to-center spacing for various sizes of tubing for frequencies of 432, 1296 and 2304 MHz.

how to design shunt-feed systems for grounded vertical radiators

A graphical design system for using your tower as a shunt-fed vertical antenna

Vertical antennas have several advantages over horizontal dipoles on the lower amateur bands, especially in those cases where the dipole cannot be raised at least one-half wavelength above ground. A recent article showed how to use a 54-foot (16.5m) tower, top loaded with a quad or Yagi, as a grounded vertical radiator on 40 and 80 meters. However, to properly design the shunt-feed matching system for these two lower bands required the use of a good quality impedance bridge. Once the complex input impedance had been determined, a graphical method was used to calculate the components required to match that impedance to a 50-ohm transmission line.

This antenna system generated a great deal of interest, but since few amateurs have access to an RX impedance bridge, they were unable to use this technique to adapt their own towers for use on the lower amateur bands. For this reason I decided to make a series of measurements which would be used to generate a set of graphs which would simplify the design of shunt-fed vertical radiators. These graphs are presented in this article.

First, a series of antenna tests were conducted by scale modeling to determine the electrical height of towers which are capacitance loaded by a typical Yagi beam or cubical quad. Further tests were conducted to determine how long the gamma-type shunt feed rod had to be to permit the use of a practical L-network for matching to 50-ohm coaxial cable.

All tests were made with an aluminum-tubing gamma rod about 1 inch (25mm) outside diameter, spaced 10 ±2 inches (20.3 to 30.5cm) from one leg of the tower. This size was chosen for maximum physical and electrical stability as well as high conductivity. The resultant design curves show the electrical height of the tower, required gamma rod length, and series capacitance, $C_s$, required to cancel the inductive reactance of the gamma rod. The parallel matching capacitance, $C_p$, is also given (fig. 1). The series and parallel capacitors should both be air variables so the matching system can be adjusted to provide as low vswr as possible.

using the curves

The graph of fig. 2 shows the relationship of physical height to electrical height of a thin wire (calculated from
measured electrical height of a 1\(\frac{1}{2}\)-inch (38mm) diameter conductor (which coincides very closely with the predicted electrical height of a thin conductor), and a tower 1 to 2 feet (30 to 61cm) in cross section, top loaded with a Yagi or cubical quad. If you wish to use your present tower as a vertical antenna for the lower bands, you can determine its electrical height from the data presented in fig. 2.

The data in fig. 3 is for use on the amateur 7-MHz band and shows the length of the gamma rod and required series capacitance for towers up to 90 feet (27 meters) high (about 3/4 wavelength on 40 meters). Towers which are taller than this will produce a large lobe of high-angle radiation that reduces the radiation at lower vertical angles. Some shorter towers may actually be shorter, physically, than the recommended gamma rod; in that case more parallel capacitance will be required to match the system to 50 ohms. Fig. 4 shows the same type of data for the 80-meter band (towers higher than 180 feet [54 meters] exhibit the large, high-angle lobe).

The data in fig. 5 is for use on the 160-meter band. Note that a tower which has an electrical height of 90 feet (27 meters) requires a gamma rod which is 60 feet (18 meters) long. Since a 43-foot (12m) tower with a Yagi represents an electrical height near 90 feet, a 60-foot gamma rod is obviously an impossibility. The use of a shorter gamma rod and more parallel capacitance may provide a match to 50 ohms, but in this case an rf bridge and graphical solution will save a lot of time.\(^3\)

Note that for towers with electrical heights near 53 and 70 feet (16.2 and 21.3 meters), a gamma rod approximately 20 feet (6.1 meters) long will provide operation on both 80 and 40 meters (the rod is about a quarter-wavelength long on 80 meters, one-half wavelength long on 40). For operation on both 80 and 160 meters, a similar coincidence occurs for towers which are electrically near 110 and 135 feet (35.5 and 41.1 meters) high. In this case a gamma rod approximately 40 feet (12.2 meters) long will provide operation on both bands. In either of these dual-band systems adjustments of the parallel tuning capacitor, \(C_p\), will compensate for differences from the specified gamma rod length.

The electrical height of towers higher than 120 feet (36 meters) can be extrapolated by adding about 35 feet (10 meters) for a three-element 20-meter Yagi with a quarter-wavelength boom (about 16 feet or 5 meters); add about 45 feet (13 meters) of electrical height for a multielement beam such as the Hy-Gain TH6DXX. A two-element 40-meter beam adds 50 to 60 feet (15 to 18 meters). Although cubical quads add about 25 feet (7.6 meters), multi-element quad designs add little more because the elements are well away from the top of the tower and insulated from it.

---

\(^3\) Note that for towers with electrical heights near 53 and 70 feet (16.2 and 21.3 meters), a gamma rod approximately 20 feet (6.1 meters) long will provide operation on both 80 and 40 meters (the rod is about a quarter-wavelength long on 80 meters, one-half wavelength long on 40). For operation on both 80 and 160 meters, a similar coincidence occurs for towers which are electrically near 110 and 135 feet (35.5 and 41.1 meters) high. In this case a gamma rod approximately 40 feet (12.2 meters) long will provide operation on both bands. In either of these dual-band systems adjustments of the parallel tuning capacitor, \(C_p\), will compensate for differences from the specified gamma rod length.
matching capacitors

Since the reactance of the series capacitor, \( C_s \), is quite large except in those cases where the tower is approximately a quarter-wavelength high, this capacitor should have a breakdown rating of about 1000 volts for transmitters up to about 200 watts output. For transmitter powers of 2000 watts this capacitor should have a breakdown rating of 5000 volts or more.

Where large capacitance values are recommended, it is suggested that at least half be variable with the rest made up with fixed padding. Note that both the stator and rotor of the series capacitor must be isolated from ground.

The ideal matching network for this antenna system would use two vacuum-variable capacitors. These capacitors are not seriously affected by humidity or changes in barometric pressure, and they can be connected to small geared motors so they can be controlled remotely from the operating position. A 300-pF vacuum variable rated at 7500 volts, and a 1000-pF vacuum variable with a 2000 volt rating should handle practically any legal amateur transmitter with low vswr.

A remote-control system that I have used for several years is shown in refer-

![Diagram](image-url)

**fig. 2. Physical vs electrical height of towers top loaded with Yagi beams or cubical quads.**
ence 1. It's obviously a lot easier to remotely control the matching system from your hamshack than it is to traipse out to the backyard in snow, sleet and rain each time you want to shift your operating frequency.

construction

A typical gamma rod installation is shown in fig. 6. On my vertical antenna the gamma rod is mounted with PVC each side of the PVC pipe, about 1 inch (25mm) in from each end (see fig. 6). Stainless-steel hose clamps are run through the slits in the PVC pipe and around the vertical member.*

If you wish, the same tower may be used on more than one lower-frequency band — simply install gamma rods on more than one leg of the tower. You can use separate capacitance matching systems or remotely controlled vacuum-

fig. 3. 40-meter vertical. Gamma rod length and series capacitance vs electrical height of tower. Recommended parallel capacitance to match 50-ohm transmission lines is 320 pF (at least 100 pF of which should be variable).

*The author has assembled several pages of how-to hints and additional constructional information which is available from him for the cost of printing and mailing. A self-addressed, stamped envelope to the author will bring a summary of contents and cost.

insulators spaced about 10 feet (3 meters) apart. The insulators are made from 1-inch diameter (25mm) PVC water pipe. The movable shorting bar is made from the same material as the gamma rod.

To attach the PVC insulators to the gamma rod, first notch the ends so one end fits around one leg of your tower, the other end around the gamma rod. Then cut half-inch (13mm) long slits on variables, depending upon your operating requirements. A vertical tower antenna system which I use successfully on both 40 and 80 meters is described in reference 1.
ground requirements

Remember that the vertical element is only one-half of a vertical antenna system — the vertical element must operate against a good ground plane or the ground losses will be so high that the antenna performs poorly. The so-called ideal ground system consists of short vertical antennas, consult the excellent series of articles by W2FM.5-8

The tower which you use to support your higher frequency antennas can easily be used as a practical antenna system for 40, 80 and 160 meters. The graphs presented here will help you to design the necessary shunt-matching system, but note that since conditions vary from one location to another, some adjustments will be necessary to obtain a low vswr. However, with an swr bridge installed near the base of the vertical (very short leads), alternately adjust the series and parallel tuning capacitors until the reflected power approaches zero. If the amount of parallel capacitance for low vswr seems excessive, make the gamma rod slightly longer.

The setting of the series capacitor is rather critical because reactance changes

120 equally-spaced, quarter-wavelength radials, but even such an elaborate ground plane as this still introduces about 2 ohms of series loss resistance into the total radiation resistance. Since short vertical antennas are characterized by relatively low radiation resistance, ground resistance loss is higher, proportionately, than it is with vertical elements which are quarter-wavelength or more. A complete discussion of ground system requirements is contained in reference 4. For more information on

fig. 4. 80-meter vertical. Gamma rod length and series capacitance vs electrical height of tower. Recommended parallel capacitance to match 50-ohm transmission lines is 650 pF (at least half should be variable).
fig. 5. 160-meter vertical. Gamma rod length and series capacitance vs electrical height of tower. Parallel capacitance required to match 50-ohm transmission lines is approximately 1300 pF.

sharply near zero so it may take several tries before you can get the capacitor set exactly right. However, with a good ground system, the shunt-fed grounded tower can provide a very efficient antenna system for relatively little cost.

fig. 6. Construction of the shunt feed system for grounded vertical radiators. The spacers are made from PVC water pipe.

references
The high-gain 1296-MHz array described in this article, which I call the "blowtorch array" and which consists of eight 13-element Yagis arranged in a circle, is light weight, presents little wind resistance, can be rotated with a small TV rotator, and provides gain equivalent to that of a 5-foot (1.5 meter) dish. The Yagis, based on a design by W2CQH, use slightly shorter directors than he specified and are designed for use with low-loss 75-ohm CATV coaxial feedline.

yagi construction

The parasitic elements of the Yagis are lengths of number-14 (1.6mm) OD copperweld wire, soft-soldered to a boom made of ¼-inch (6.5mm) thick-wall brass tubing, 36 inches (91.4cm) long as shown in fig. 1. The copperweld elements provide both physical strength and high electrical conductivity, both of which are required for effective operation.

Before cutting the directors, make up a simple template as shown in fig. 2 so that each of the directors is precisely the same length. This is extremely im-

*Any specific information desired regarding this array can be obtained by enclosing a self-addressed stamped envelope with inquiry to Paul F. Magee, W3AED, R2 Box 432, Berlin, Maryland 21811.
important because very slight differences in length will adversely affect the performance of the antenna.

The driven element is a delta-matched dipole of number-14 copper-weld which is soldered to the boom. The delta-matching system consists of two pieces of number-14 soft copper wire soldered to the dipole — this is fed by a balun made from two pieces of 1⁄4-inch (6.5mm) OD copper tubing, 1½ inch (38mm) long, which are soldered on top of the boom as shown in fig. 3. Place the forward end of these two tubes as close as possible to the driven element to minimize lead length to the delta match.

To hold the two balun tubes in the proper position while you are soldering them, bend a small piece of sheet aluminum into a vee which can be held loosely in a vise. Note the short number-14 stud which is soldered between the quarter-wavelength balun tubes — this provides a convenient place to solder the shield of the 75-ohm coaxial phasing.
Use of a template is recommended to assure that each of the directors is precisely the same length. For best results, cut each of the directors slightly longer than necessary and file off the ends until each element just passes through the gauge.

After the two copper balun tubes and all elements have been soldered to the boom, strip off the outer jacket and shield from a section of 75-ohm TV feeding (which has a larger diameter than RG-59/U). Fold the balun wire into a U and insert it into the balun tubes. Connect the center conductors to each side of the delta match.

The antenna mount consists of a center hub of 1/8-inch (3mm) thick galvanized steel, 8 inches (20cm) in diameter, to which is attached a spider-shaped arrangement of 3/4-inch (19mm) aluminum tubes, each 31 inches (79cm) long. Short tabs on the top and bottom of the center hub provide space for the U-bolts which are used to attach the array to a mast.

The aluminum tubes are attached to the hub with 10-32 screws and strengthening members made from 3-inch (76mm) lengths of 1-inch (25mm) square aluminum channel (see fig. 4). The Yagis are attached to the ends of these tubes with special clamps which allow the antennas to be oriented parallel to one another.

The Yagi clamps, shown in fig. 5, are made from 2-inch (51mm) lengths of 1-inch (25mm) square aluminum channel which is attached to the aluminum tubes with small U-bolts made from ¼-inch (6mm) threaded steel stock. Two small notched aluminum blocks are used to hold the antenna boom to the channel (cut the notch...
slightly smaller than the diameter of the boom so the antennas are held very rigidly).

Be sure to use brass nuts on the steel U-bolts. The combination of aluminum clamps and brass hardware doesn’t seem to cause any problem as my array shows no ill effects although it has been exposed to the salt air at my station for more than two years.

**matching harness**

The matching system for the blowtorch array is made up of a system of 50-ohm quarter-wave matching transformers and 75-ohm coaxial feedlines 16 half-wavelengths long (48 inches or 122 cm). A schematic diagram of the system is shown in fig. 6. Since the 75-ohm matching lines are an integral number of half-wavelengths long, the 75-ohm input impedance of each of the antennas is repeated at the opposite end. Since two 75-ohm feedlines are connected in parallel at points A, C, E and G, the impedance at each of these points is 37.5 ohms. This is transformed to 75 ohms by a 50-ohm quarter-wave transformer. These transformers are connected in parallel at points B and F, so the impedance at these points is 37.5 ohms. This is transformed to 75 ohms with another 50-ohm quarter-wave transformer (B-D and F-D).

When connected in parallel at point D and transformed with another quarter-wave transformer, the input impedance provides a close match to the 75-ohm feedline. Note that the 8-wavelength matching lines are not connected to adjacent antennas, but to antennas on opposite sides of the array.

The quarter-wavelength matching transformers are soldered to a 3x5-inch (8x13 cm) copper sheet as shown in the photograph of fig. 7. The outer conductor of each quarter-wave transformer consists of a 3/16-inch (5 mm) OD copper tube, 1/2 inch (38 mm) long. Short lengths of RG-58/U coax (strip-
ped of the outer shield and jacket) are threaded through these tubes. Short stubs of number-14 wire, about 3/8 inch (10mm) high, at the feedline end of each of the transformers provides a convenient point for connecting the outer shield of the 75-ohm feedlines. The completed transformer is mounted in a waterproof enclosure which is installed at the center of the array.

be checked individually before they are installed on the large array. First check the vswr and make adjustments as necessary to the delta match for a vswr of 1.2:1 or less. Then check the lobes on each side of the main pattern. If they are not at least 9 dB down, the antenna is not working correctly. This can be checked by connecting a low-power 1296-MHz signal source to the antenna

When soldering the tubes to the copper sheet make sure they are soldered from one end to the other. You can use a small torch for this, if you wish, but I suggest a husky 200-watt soldering iron. When the transformer assembly has cooled off, the rosin flux can be removed with lighter fluid. (Acid flux can also be used but thoroughly clean off any residue with hot water, baking soda and a tooth brush before you install the sections of RG-58/U.)

testing

Each of the 13-element Yagis should and measuring the relative field strength about 50 feet (15 meters) in front of the antenna.

When the blowtorch array is completely assembled check the field strength about five feet (1.5 meter) in front of each Yagi; if the phasing system is working properly the field strength in front of each of the antennas should be the same.

reference

Meet the two and only.

The HAL DKB-2010 Dual Mode keyboard is one of the most sophisticated products ever offered to the radio amateur. It's an all solid state keyboard that allows you to send either RTTY or CW - with more ease, more versatility than anything you've ever seen before.

In the RTTY mode, you can operate at standard data rates of 60, 66.75 or 100 WPM, as well as an optional 132 WPM, 100 baud. In addition to the complete alphanumeric keys, you get 17 punctuation marks, 3 carriage control keys, 2 shift keys, a break key, 2 three-character function keys, a "DE-call letters" key and a "Quick brown fox..." test key.

In the CW mode, you can send at speeds anywhere between 8 WPM and 60 WPM. You can also adjust dot-to-space weight ratios to your liking. For CW, you have all alphanumeric keys, plus 11 punctuation marks, 5 standard double-character keys, 2 shift keys, a break-for-tuning key, error key, "DE-call letters" key, plus 2 three-character function keys. Output interfacing is compatible with cathode keying or grid-block keying. A side tone oscillator and built-in speaker allow you to monitor your signal — with adjustable volume and pitch controls.

The DKB-2010 also has a three-character memory buffer which operates in either the RTTY or CW mode, allowing you to burst type ahead without losing characters. A 64-character memory buffer is also available as an option. Key function logic in either mode is governed by LSI/MOS circuitry. All key switches are computer grade.

The DKB-2010 is available assembled or in kit form. Should you choose the kit, you'll find construction easy — the unit consists of three assemblies: power supply board, logic PC board, keyswitch PC board, and pre-assembled wiring harness.

Anyway you look at it - as an easy-to-build kit, a complete assembly, as a CW keyboard, or an RTTY keyboard, the HAL DKB-2010 is a real breakthrough for every amateur. It adds a whole new dimension to the exciting world of amateur radio. Once you've used the DKB-2010, you'll wonder how you ever got along without it!!

Prices: $425 Assembled; $325 Kit.
measuring complex impedance
with an
swr bridge

Accurate impedance measurements can be made over a wide frequency range using a vswr bridge and the simple second-data method described here

Knowledge of the resistive and reactive components of a load is very useful in antenna work, but few amateurs, unfortunately, have the necessary equipment for making the necessary measurements. The simple impedance bridges found in many amateur workshops will measure resistive loads from about 5 to 400 ohms, and if the load is reactive, a true null will not be obtained. For low impedances the readings of these simple instruments approximate the resistive component while for high impedances the readings approximate the total impedance. In between, the readings are a poor approximation to either.

The RX meter, which can accurately evaluate both the resistive and reactive components of a load, on the other hand, is considerably more complex than the simple rf impedance bridge, and is somewhat more difficult to build and operate, especially above about 30 MHz. A practical amateur RX meter described recently has relatively good sensitivity and a moderate impedance range and doesn’t require much drive power, but requires a separate inductance assembly for each band of frequencies. Other homebuilt instruments for measuring complex impedances are described in references 2, 3 and 4.
second-data impedance measurement

Because of these problems and others most amateurs try to avoid the measurement of unknown complex impedance. Fortunately, however, there is an alternative: the second-data method. This method permits relatively accurate measurement of complex impedance with a vswr bridge and an external resistor. Since most amateurs have vswr bridges this is a technique that should not be overlooked. Since vswr bridges which work to 600 MHz and above are readily available, this method has the additional advantage of extending the frequency range.

![Soldered Together](image)

fig. 1. Simple coaxial adapter for the series resistor is made from two back-to-back PL-259 connectors.

In the second-data impedance measuring system the vswr of the load is first measured in the normal fashion and then the vswr is measured with a resistor in series with the load. These two sets of data are adequate to specify the resistive and reactive components of the load. You merely look up the two vswr measurements in a table such as that shown in table 1 and read off the resistive and reactive components. If you wish, the resistive and reactive values may also be plotted on a Smith chart, as will be discussed later.

For measurements up to 20 MHz or so, the series resistor may be soldered in series with the load or clipped in. For higher frequency measurements or when a coaxial line is used, the series resistor should be installed as the center conductor of an appropriate adapter as shown in fig. 1. The vswr is then measured with and without this adapter in the line.

For best results measurements should be made with a vswr bridge that has good linearity characteristics. The resistance in series with the diode detectors within the bridge should have as high a value as possible, at least 10 kilohms. Check your vswr bridge for no return power (vswr = 1:1) with a good quality dummy load. You can check its accuracy at other standing-wave ratios by using standard composition resistors (with short leads) as loads. The vswr of the load is given by

\[
\text{vswr} = \frac{R}{Z_0} \quad \text{or} \quad \frac{Z_0}{R}
\]

whichever is greater than 1. Loads of either 150 ohms or 16.67 ohms, for example, will result in a vswr of 3.0:1 in a 50-ohm system.

The vswr to series complex impedance conversion information shown in table 1 for 50-ohm systems is based on the use of a 27-ohm series resistor. The resistive and reactive values were calculated with an error of less than one percent and rounded off to the nearest ohm.*

To illustrate the use of this table, assume that an unknown load exhibits a vswr of 2.4:1. When the 27-ohm resistor is placed in series with the load the measured vswr is 1.8:1. From table 1, the resistive component of the load is 33 ohms; the reactive component, 32 ohms.

*More detailed, computer-generated tables for both 50- and 75-ohm systems are available from the author for $4.00, postpaid. The tables are calculated for 27-ohm series resistance with 50-ohm systems and 39-ohm series resistance with 75-ohm systems.

</table>
Since the entire range of possible VSWR combinations for a series 27-ohm resistor is given in Table 1, if you measure a larger VSWR than shown, there is an error in measurement. For example, if you measure a load VSWR of 2.0:1, then install the 27-ohm resistor and measure the VSWR again, a new VSWR measurement of 4.0:1 reveals an error in measurement as it is outside the range of values given.

Smith chart computation

If you wish to use the Smith chart to make your impedance calculations, the series resistor does not have to be the same value as that used in computing the chart (27 ohms for 50-ohm systems) — it can be any reasonable value. Assume, for example, that the series resistor is 25 ohms, the measured VSWR of the unknown load is 3.0:1, and with the 25-ohm resistor in series with load the VSWR is 2.0:1.

To compute the complex impedance of the unknown load you must first plot two circles on the Smith chart as shown in Fig. 2. The first circle, circle 1, is a constant VSWR circle corresponding to a measured VSWR of 3.0:1 and intersects with 3.0 on the real axis. This circle passes through all the resistive and reactive pairs which produce a VSWR of 3.0:1, so the impedance of the unknown load must fall somewhere on this circle.

The second circle, circle 2, is another constant VSWR circle, this one corresponding to the 2.0:1 VSWR measured with the 25-ohm resistor in the line. The final circle, circle 3, which is offset by the amount of resistance in series with the line for the second VSWR measurement, represents all the values on circle 1 with \( Z_0/25 \) (0.5 resistive) added to each point. This circle is easily drawn by adding 0.5 resistive to both points where the circle crosses the real axis (at 0.33 + 0.5 = 0.83 and 3.0 + 0.5 = 3.5), and plotting a circle through these two points.

Circle 3 intersects circle 2 at two points. Both points have the same resistive and reactive values, but the reactive values have opposite signs. To transform the intersection on circle 2 to the actual value of the unknown load, 0.5 ohm resistive must be subtracted from the values on circle 2. In this case the intersection on the upper half of the chart is 1.05 + j0.72. Subtracting 0.5 ohm resistive yields 0.55 + j0.72. This is the original load and should fall on circle 1. If it doesn’t, you made an error in your calculations.

Since this is a normalized Smith chart, the plotted values must be multiplied by the characteristic impedance of the system, 50 ohms. This yields values of 27.5 ohms resistive and 36 ohms reactive for the unknown load. You must still determine whether the reactance is capacitive or inductive (negative...
or positive). In some cases you may know beforehand whether the reactance is capacitive or inductive (a half-wave dipole operated above resonance, for example, has an input impedance that is inductive) but in those cases where you must determine the sign of the reactance another measurement is required. After the resistive and reactive components of the load have been determined, the vswr is measured again with a capacitive reactance \((X_c \approx X_L)\) placed in series with the load. If the resulting vswr is less than the original vswr, the reactance of the load is inductive. If the resultant vswr is greater than the original vswr, the reactance is capacitive.

Things are simplified considerably when the impedance measurement can be made directly at the input terminals of the unknown load, but this is not always possible. The usual solution is to take the measurement at the end of a transmission line and use the Smith chart to refer the load back to the antenna feedpoint. Further information on this subject is provided in references 6 and 7.

**accuracy**

The accuracy of this method of impedance measurement, of course, is dependent upon the accuracy with which the vswr measurements are made. Accuracy of the second-data method is also dependent on the magnitude of the measured impedance with errors increasing with increasing impedance. However, accuracy is acceptable up to about 300 ohms, depending on the accuracy of the vswr bridge, and accuracy is quite good around the commonly used system impedances of 50 and 75 ohms.

As an example, consider the case of a quarter-wavelength vertical operating over perfect ground. Its base feedpoint impedance, theoretically, is 36 ohms. If the second-data technique is used with a vswr bridge that reads 10% high, the indicated impedance will be 36.7 ohms resistive and 12.7 ohms reactive; the bridge has introduced a small reactive component. As with any electronic measurements, good results are guaranteed only when the measuring instruments have been carefully checked and calibrated.

Super Mast
Small in a big way.

For the low profile Ham operator.

It had to happen! The enormous success of Tri-Ex's original Sky Needle—by popular demand—has brought about the design of a miniature Sky Needle for the Tri-Band Beam. We call it Super Mast.

It's a special tower for the low profile HAM operator. A rooftop-per stretching to 40-feet up. Attaches easily, simply to the side of your garage or house. A super-easy Super Mast. A top-quality Tri-Ex product. Hot dipped galvanized TOWER CORPORATION Price of this under-$300-tower, because of rising steel costs, is subject to immediate change. Order now and save!

7182 Rasmussen Avenue, Visalia, Calif. 93277

Shown here in its nested position at 21-feet, this Super Mast is supporting a three element 15 meter antenna & rotor assembly. Rush your order now. Visit or call your local Tri-Ex Tower dealer today. Price of this under-$300-tower, subject to immediate change.
**electrically-controlled phased array**

Phased array for the lower amateur bands uses hybrid couplers for electrical control of the field pattern.

On the lower frequency amateur bands, where a rotary antenna may be too cumbersome for convenience, the answer may be a phased array, with electrical instead of mechanical control of the field pattern. Such a system will also be less vulnerable to damage from ice and high winds.

The phasor, which is the heart of this system, is built around a 3 dB quadrature hybrid. Such a hybrid may be regarded as a four-port circuit element, having two input ports and two output ports (fig. 1). When both output ports are terminated by matched loads, a signal injected at either input port will divide equally between the two output ports with a $90^\circ$, or quadrature, phase difference between the outputs. Because no signal exists at the remaining input port, the input ports may be seen to be isolated from each other.

Several different designs are available to the experimenter for the construction of such a hybrid. The most compact and convenient form for the lower amateur bands, however, consists of two capacitively coupled lengths of coaxial line, of whichever characteristic impedance has been chosen for the system (fig. 2). These lengths of coaxial line will each be an electrical one-eighth wavelength at the frequency of interest, while the coupling capacitors will have a reactance equal to the characteristic impedance of the coaxial lines.

**theory of operation**

If the output ports of the hybrid, instead of being terminated by a pair of matched loads as in fig. 1, are terminated instead with identical lengths of transmission line as shown in fig. 3, the following action will take place as a signal is injected into port 1:

1. The injected signal will divide into two equal parts, one going to port 3, while the other part, after undergoing a $90^\circ$ phase shift, appears at port 4. Both signals then progress down to the ends of their terminating lines and are reflected back to their respective ports, having traveled back and forth along the line for a total distance equal to twice the actual length of the line.

2. The reflected signal returning to port 3 divides into two equal parts, one of which goes directly to port 1, while the other part, after a $90^\circ$ phase shift, goes to port 2.

3. The reflected signal at port 4 also divides into two equal parts, one of which goes directly to port 2, where it combines with the component which came from port 3. Note that each of these two components has traveled the same distance and undergone a single
phase shift of 90°. The other part of the reflected signal at port 4 undergoes a second 90° phase shift and goes to port 1. Both of the components at port 1 can be seen to have traveled the same distance, but are 180° out of phase with each other, and therefore cancel. As a result, no signal is reflected back to port 1 which is not cancelled out, and no input vswr results. It may be seen, therefore, that any equal change in the lengths of the two terminating lines will result in a phase change in the signal emerging from port 2 which is equal to twice the change in line lengths.

With this last conclusion in mind, it becomes apparent that a reactance change at ports 3 and 4 which is equivalent to that produced by a quarter wavelength, or 90° change in line length, will result in a total phase change of 180° in the signal emerging from port 2. Using lumped constants, instead of transmission lines, to terminate ports 3 and 4, the network shown in fig. 4 will accomplish the equivalent operation.

When the variable phasing capacitor in the circuit of fig. 4 is set at maximum capacitance, it becomes parallel resonant with its shunting inductors, thereby simulating an open circuit. At minimum setting of the phasing capacitor, the series capacitors are trimmed to produce a condition of series resonance, thus simulating an open quarter-wavelength of terminating line. In this manner you obtain a controlled phase shift of up to 180 electrical degrees by merely turning a knob.

Line lengths and coupling capacitances were first computed for a frequency of 7.2 MHz. Assuming a velocity of propagation factor of 0.66 for the RG-58/U cable chosen for the purpose, the transmission lines are each 135 inches (344cm) long. Coupling capacitors for 53.5-ohm coaxial cable are 414 pF. A pair of 220-pF silver mica capacitors were used in parallel. Alternatively, a 330 pF and a 100 pF capacitor were used for a second hybrid, with satisfactory results in each case. (If the system is built with RG-59/U coaxial cable for operation at the 70-ohm level, the capacitors will be about 316 pF.)

In order to determine the length of the transmission line a bit more accurately, a quarter-wavelength of line was fitted with a very small, single-turn coupling loop at one end. This assembly was then carefully grid dipped to frequency, the dipper frequency being checked on the receiver. Small bits of coaxial line were then clipped from the open end of the cable to raise the resonant frequency to the desired value. It is a great deal easier to cut a piece off than to fasten it back on, so be careful if you choose to go this route.

After the correct line length has been obtained, remove the coupling loop, double the line back on itself and cut it in two equal halves. Peel back as little covering and braid as necessary to make connections to the ends of the cables.

To check the hybrid, ports 3 and 4 are first left as open circuits and a
matched load is placed at port 2. An input VSWR reading is now taken at various frequency intervals across the band to determine how well the line lengths have been chosen. At the center frequency a VSWR of 1.05:1 or less should be possible if the line lengths and coupling capacitors are correct.

The isolation inherent in the hybrid can be checked by terminating ports 3 and 4 with matched loads, and the output at port 2 measured and compared with that obtained when the loads are not present. A pair of 51-ohm carbon composition resistors were used for this rough check, with the receiver at port 2 used as an indicator. Isolation of 20 to 30 dB was considered to be adequate for the purpose.

Once the hybrid has been checked out satisfactorily, the next step is the alignment of the reactance network. In the first place, the two inductors should be made as closely identical as possible. Both inductors should resonate at the center frequency with the phase control capacitor fully meshed. The grid dipper becomes necessary for this operation. Turns can be spread or squeezed together, and fastened with coil dope.

Once the coils have been trimmed, the phase control capacitor is turned to its minimum setting, and the series capacitors grounded, so that they are temporarily in parallel with the inductors. The series capacitors are now set so that the inductor-capacitor combination is again resonant at the same frequency of interest. Disconnect the temporary ground connection, and connect the series capacitors to ports 3 and 4 of the hybrid.

Connect a matched load to port 2 again and check the input VSWR of the complete phasor. As the phase control capacitor is rotated through its range there should be no change in VSWR.

In coupling to two separate antennas, a second hybrid, identical to that used in the phasor, appears to be the best arrangement as shown in fig. 5.

**operation**

To ensure placing a maximum signal lobe accurately in the direction of a given station, a pair of coaxial relays were hooked up as a reversing switch. The other station is first nulled out as far as possible, then the relays are actuated so that the connections to the transceiver and dummy load are reversed (fig. 5). This places a maximum signal lobe towards the selected station.

It can be seen that if a given station can be completely nulled out, the entire received signal is being routed to the dummy load, rather than to the receiver. Reversal of the order of connection by means of the relays then routes the entire signal from both antennas to the receiver. Since the effect is reciprocal, when transmitting both antennas combine to place a maximum lobe in the direction of the other station. It should not be difficult to calibrate the phase control in terms of direction so that this procedure can be omitted.

Don't expect a complete cancellation of the signal from a given station as no two antennas will have identical, perfectly circular radiation patterns. Maximum to minimum signal reports have varied from 1 to 6 S-units, with rare instances where the signal dropped completely into the noise level. If you consider that one antenna puts out a signal of 100 power units, while the other only puts out 95 units in a given direction, then the best possible cancellation

![fig. 3. Quadrature hybrid terminated by equal lengths of transmission line.](image-url)
would still leave 5 units of signal. A ratio of 195 to 5 in power is about 14.1 dB, slightly more than 2 S-units. Therefore it should be apparent that the two antennas should be made as identical as possible.

Another factor in the operation of a system of this type is the spacing between the two antennas. If they are close together, there will be coupling present which will greatly affect the power distribution between them. With a spacing of around 120 feet (37m), the input vswr of the system varies over the phasor range from 1.0:1 to 1.2:1.

While any two relatively identical vertical antennas should perform satisfactorily, the pair I used were less than 15 feet (4.57m) in height, resting on a glass jar set on the ground. As this was a temporary experimental installation, a rather skimpy ground system of eight radials, each 30 feet (10m) long, was used. Matching was accomplished with an L-network.

It appears that the phasing system could be applied to two colinear horizontal dipoles. In addition to being, in many cases, easier to erect, the end-on arrangement of the radiating elements might be expected to show lower mutual coupling between the elements.

While not giving a full 360° coverage as uniformly as vertical antennas, the horizontal system might offer an interesting area for investigation.

It is felt that the results obtained with this experimental (and admittedly temporary) installation justify the concept of omnidirectional control of the antenna pattern. Although the wide spacing of the elements of the antenna system results in more lobes than a beam, the total area covered by the lobes should be about the same, with no loss of signal strength in directions of maximum signal as a result of the increased spacing. A vertical antenna system of this kind should offer much to the low-frequency DX man by combining the low-angle radiation of the vertical antenna with control of the directivity.

*Ham Radio*
wide bandwidth
bow-tie antenna
for eighty meters

Discussion of a bow-tie antenna design using galvanized-steel wire that provides low swr performance over the entire 80-meter amateur band.

One of the problems requiring a decision when you establish a station is the selection of an antenna or group of antennas for the bands on which you want to operate. To make the best use of your environment and space available requires some study and planning.

In the case of the limited space of a city lot, especially for an 80-meter antenna, special steps may be needed for satisfactory results. A major consideration for an 80-meter antenna is the portion of the band you intend to use. The ordinary single-wire horizontal dipole, when used on this band, for example, will not work well over the entire band without some sort of antenna tuner or matching system. Verticals have the same limitations, but this article is concerned only with a horizontal antenna.

A typical horizontal dipole, resonant at 3.75 MHz, will approximate a series-
resonant circuit as shown in fig. 1. Resistance $R$ represents the radiation resistance which will be about 50 ohms. The inductive and capacitive reactances, $X_L$ and $X_C$, with a $Q$ of 14 will be about 700 ohms (14x50 ohms) at the resonant frequency.

Fig. 2 shows a swr vs frequency curve for a horizontal, single-wire antenna, resonant at 3.75 MHz, measured and used as a standard of comparison for the experiments that follow. Tests made at four other amateur stations show the curve of fig. 2 to be typical for antennas of this type.

One important fact must be noted at this point: the majority of swr bridges made for amateur use will not provide accurate readings on the 80-meter band because of the non-linearity of the germanium diodes used in the simple bridge circuits. A Heath HM-102 swr bridge was used to obtain the curves presented here. This unit checked very closely with a Waters 365A reflectometer as well as with a standard Bird wattmeter. The typical, simple bridge will measure swr as much as 35% low on 80 meters.

Using the values of fig. 1, the inductive reactance of the antenna at 4 MHz will be $(4/3.75)700 = 747$ ohms; the capacitive reactance, $(3.75/4)700 = 656$ ohms. The net reactance is $747 - 656 = 91$ ohms (inductive). At 3.5 MHz the inductive reactance will be $(3.5/3.75)700 = 653$ ohms; capacitive reactance is $(3.75/3.5)700 = 750$ ohms, and the net reactance is $750 - 653 = 97$ ohms (capacitive). Neglecting the resistance change with frequency, which is small, the impedance at 4 MHz will be approximately $50 + j91$ ohms; at 3.5 MHz the impedance will be approximately $50 - j97$ ohms.

Fig. 2 shows the swr variations across the 80-meter band for the single copper-wire antenna with the maximum points at about 5.6:1 on the band edges. To reduce the swr (to broaden the frequency range of the antenna) you can reduce the $Q$ by reducing the reactance or raising the radiation resistance. One method of reducing the reactance is by using a larger diameter antenna conductor. However, in most cases this is impractical at low frequencies. To reduce the $Q$ of the single-wire antenna from 14 to 10, for example, would require a diameter of 640 mils or 0.64 inch (16mm). The use of RG-8/U coaxial cable, with the inner and outer sections
connected in parallel, reduced the Q of the antenna to about 12.

A much more practical method of increasing antenna bandwidth is by using the bow-tie or fan configuration shown in fig. 3. With a wire separation of 7 feet (2.1 meters) or more and copper wire, the Q can be reduced to about 10. This brings the swr at the band edges down to about 3.8:1. For swr no higher than 2:1, the bandwidth is increased to 190 kHz.

double-bazooka antenna

The so-called double-bazooka or coaxial antenna is another modification for increasing the bandwidth of the basic horizontal dipole. However, the results were disappointing in the tests I made with this system. With new RG-58/U cable and very careful construction, with open-wire line for the end sections, the best I could obtain was an swr of about 3.5:1 at the band edges, an 8% improvement over the bow-tie (see fig. 3). The use of RG-8/U or RG-11/U for this antenna was not tried.

On the basis of the considerably greater cost and work required to build the double-bazooka antenna, it compares poorly with the bow-tie. The possible balun characteristic it is supposed to have is difficult to determine and of doubtful value.

galvanized wire

About two years ago, with more antenna experimenting in mind and copper wire in short supply, I obtained a roll of galvanized steel electric-fence wire at a farmers' supply store. When I built a single-wire dipole with this wire, a considerable lowering of swr was noted. The same wire in a bow-tie showed an swr of about 2.5:1 at the 3.5- and 4-MHz band edges. When I checked the radiation resistance at resonance, it was found to be about 50% higher than with copper, or about 75 ohms for a single wire and 50 ohm for the bow-tie (see fig. 4).

Speculation as to the reason for the increased radiation resistance, as well as how much antenna loss may have increased because of the higher resistance of this wire, led to quite a bit of research in reference books and experimenting.

First off, the wire I used is designated as number-16, but this refers to the...
size before the zinc galvanizing is applied. Checking the wire table shows the diameter of number-16 as 50.8 mils (1.3mm). When checked with a micrometer, the wire measured 62 mils (1.5mm). The diameter of number-14 wire is 64 mils (1.6mm) so this wire is very nearly the equivalent. Although the use of galvanized wire for an antenna is by no means anything new, information on its rf characteristics is difficult to find. After failing to find anything in the antenna reference books, some experimenting led me to results that indicate, I think, a loss figure that is not too high when compared to copper.

The resistance tables show zinc with two to three times the dc resistance of copper. And, because of skin effect, most of the antenna rf current will be in the zinc coating. In an effort to get a comparison, equal lengths of number-14 copper wire and number-16 galvanized-steel wire were wound on identical forms and checked for Q at 3.75 MHz with a Q-meter. This test showed the copper-wire coil had a Q about six times that of the galvanized-wire coil. From this data it was assumed that a 6-to-1

ratio of rf resistance was fairly correct at 3.75 MHz.

The actual loss resistance of a copper-wire antenna at 3.75 MHz is another thing that is very hard to find in the reference books. The loss resistance is usually considered to be "extremely low" or "negligible," and the only book I could find with anything like a definite statement was Transmission Lines, Antennas and Waveguides. On pages 113 and 114 the authors stated that, when using 80-mil (2mm) copper wire at a frequency of 3 MHz, a dipole with 64 ohms load resistance at resonance will have 3% of the 64 ohms as loss resistance. This works out to be 1.92 ohms, and should be nearly the same at 3.75 MHz as the shorter length would just about balance the effect of the

higher frequency. For number-14 copper wire, the smaller diameter should raise this to about 2.15 ohms $(1.92\sqrt{80/64})$.

Fig. 5 shows the relationship of the loss resistance and the radiation resistance. The percentage of power lost in heating the wire, of the total applied to the antenna, would be $R_1/(R_1 + R_2) = 2.15/64 = 3.4\%$; the percentage radiated would be 100 - 3.4 = 96.6%. For the galvanized-steel wire, we can assume the loss resistance to be six times 2.15 or 12.9 ohms. It is assumed that this figure for the single galvanized wire will remain substantially the same with average variations in antenna height and inverted-vee angle. For the single galvanized wire, the loss ratio is 12.9/75 = 17.2%, yielding an efficiency of 82.8%.

Because the two wires of the bow-tie are in parallel for the antenna current, the effective loss resistance should be about one-half that of the single wire. For the copper and galvanized bow-ties, therefore, the loss resistance should be about 1.08 ohms and 6.45 ohms, respectively. The relative frequency response of the antennas that have been checked

![fig. 6. In this modification of the basic bow-tie antenna, the ends are tied together. Bandwidth is affected little by spreads from 6 to 16 feet (1.8 to 4.9 meters). Radiation resistance of this antenna is 50 ohms at 3.75 MHz.](image-url)
can be expressed by the bandwidth over which they can be used with no more than a 2:1 swr (see table 1). The figure of 2:1 is used because this is the maximum swr specified by many manufacturers for their transmitters or transceivers. An swr of 2:1 is also the value above which line loss begins to mean something.

**bow-tie antennas**

A useful modification to the basic bow-tie antenna is that of tying the two wires together at the ends as shown in fig. 6. This shortens each side by about one-half of the end separation as shown. The overall length of 103 feet (31.4 meters) is very desirable where space is limited. The end connection can be made by using light-weight aluminum spreaders, a wood spreader with wire connector, or any other method that provides the mechanical spread and the electrical connection.

The spread of the wires can be either horizontal or vertical. A variation of spread from 6 to 16 feet (1.8 to 4.8 meters) makes very little difference in the swr characteristic. A very wide spreader, however, results in a proportionate reduction in overall length. Fig. 7 shows one arrangement that worked very well with swr performance slightly better than the standard spread.

A simple and economical L-network tuner, as in fig. 8, will allow an antenna cut for resonance at 3.75 MHz to be used over the entire 80-meter band with no more than 1.5:1 swr at the transmitter terminals. The maximum swr on the feedline is only about 2.6:1 so with RG-8/U feedline, the line loss due to swr would be about 0.34 dB at 3.5 MHz and 0.44 dB at 4 MHz, practically negligible amounts.

A comparison of the associated feedline loss of the two bow-tie antennas

Bow-tie antennas can also be built with a very wide spread as shown here. As well as shortening the overall length of the antenna, this slightly improves the SWR performance. Radiation resistance of this antenna is 50 ohms at 3.75 MHz.

Table 2 shows that the price paid in increased loss from the use of the galvanized steel wire is small enough to justify its use for the resultant broadband characteristic of the antenna. Its lower cost, compared to copper, is a fringe benefit. The durability of this wire, if my case is typical, is very good. The same wire has been up for two years with no visible rust. A coating of varnish or lacquer could be applied before putting the antenna up, if desired.

The operating Q of the bow-tie antenna can be reduced further by using the parallel compensating circuit shown in fig. 9. This circuit is simple, inexpensive and will work with any dipole to some extent. It makes use of the principle that a parallel tuned circuit has the opposite reactance variation on each side of resonance as that of a series resonant circuit. When connected as shown in fig. 9, the parallel network will cancel some of the series reactance exhibited by the antenna on each side of resonance. The values of inductance and capacitance were determined by experiment for best results. The capacitance is 2500 pF and the coil is adjusted by means of a grid dipper to resonate with the capacitor at 3.75 MHz.

By shortening or lengthening this antenna, the resonant point can be moved higher or lower to obtain the desired coverage. Eight inches (20.3 cm) of change, in each wire, will produce about 80 kHz frequency shift.

Considerable time and effort have been spent to answer two obvious questions: Why does the bow-tie antenna exhibit broader response than a single
wire, and why does the use of galvanized steel wire show the same effect? As for the first question, one reference book indicated that the bow-tie arrangement effectively increased the conductor size. That does not satisfy me. The most logical explanation seems to be that the two parallel wires reduce the inductance while at the same time increasing the capacitance between the halves of the antenna and the ground. The reduction in reactance is great enough to more than compensate for the reduction in radiation resistance, resulting in lower Q.

As to why galvanized steel wire increases the bandwidth of the antenna, it is thought that the 60% increase in feed-point resistance at resonance (in the bow-tie), as indicated by an antenna noise bridge, must be the reason for the lowered Q. Part of this increase is due to the higher loss resistance, of course, and this has been calculated to be about 6.45 ohms while the actual increase is 20 ohms. This would require a ratio of 20/1.08 or about 18.5 times as much rf resistance in the galvanized as the copper antenna. Even considering the limits of the Q meter for making coil comparisons, this is much too great an error to believe possible.

It has been noticed, however, that the galvanized wire, for a given resonant frequency, is about 4% shorter than the copper wire. This could be explained, as suggested by WB0BGH, by a “velocity factor” effect of the current flow slowing down on the higher resistance wire.

This might raise the radiation resistance and lower the Q.

One experiment was tried using number-26 copper wire instead of galvanized steel. The swr at the band edges of 80 meters was about 3.2:1 and the radiation resistance about 65 ohms. The rf resistance of number-26 copper, according to the wire table, should be about 85% of the single galvanized-steel wire.

The transmission line used for all tests and swr curves was 88 feet (26.8 meters) long, checked out with a noise bridge for one-half wavelength at 3.75 MHz. It was found experimentally that the circuit of fig. 10, with the values shown, when inserted between the transmitter and feedline, modified the swr curve to that shown in fig. 11. For this result, however, the transmission line must be close to one-half wavelength long. To obtain the averaging out effect the transmission line should be within 5% of one-half wavelength long.

The simple circuit of fig. 10 replaces that of fig. 8 when the parallel compensating circuit at the antenna and a half-wave feedline are both used. This brings the system to the point where no tuning
is needed at all, with very low swr at the transmitter output terminals.

**operation**

The ability to work across the entire band with no more than 1.5:1 swr, as shown in fig. 11, provides very smooth operation. A variable antenna tuner with a coax fed copper antenna will also cover the 80-meter band but with a much more complicated tuner and with much higher line loss.

Swr curves were run with and without a balun at the center of the antenna. Both straight-core and toroid types were tried. The only observed difference was a downward shift in resonant frequency by about 50 to 75 kHz. Substitution of number-14 galvanized wire with an actual diameter of 75 mils (1.8mm) resulted in a very small change as compared to number-16 wire. A third wire, strung between the two wires of the basic bow-tie, was tried with very little change.

One thing I did notice was that twisting the two wires together at the center, even for 2 or 3 feet (61 to 91cm), raised the swr about 6%. This effect led me to try bracing the two wires about 10 inches (25.4cm) apart at a point about 18 inches (45.7cm) out from the meeting point, but no improvement was observed.

I experienced no difficulties from the wires getting twisted or tangled after the antenna was installed. Winds up to 60 mph (97 kmh) have given no trouble.

All experimental work was carried on jointly with WBURR who first suggested the use of the bow-tie arrangement with which he had already done considerable experimenting. Both he and WBSAY are using the antenna with very satisfactory results.

**reference**

Put together a wide variety of exciting new products and a dynamic young company on the move and you have DENTRON . . . dedicated to Making Amateur Radio More Fun.

**HERE’S A REAL PLUS**

You will add a real plus to your SSB station when you give it complete 160-meter receive and transmit capability with the exciting new Dentron 160 XV Transverter. Just two simple connections with no modifications and you’re on the air.

Let the Dentron 160 AT antenna tuner solve your 160-meter antenna problems the easy uncomplicated way. This transmatch will load any random length antenna from a short whip to an extra-long wire. Use it with virtually any existing HF antenna you already have. Handles maximum legal power. Use with the 160-XV or any other 160 meter equipment requiring a 52 ohm antenna.

**Dentron 160 AT Antenna Tuner** $59.95 ppd. USA

- 5 watts drive gives 100 watts DC input
- 3.8 to 4.0 MHz input
- Matches 50 ohm antenna
- Built in 110/220 V 50/60 Hz supply
- Units are available for the 2 MHz MARS frequency

**Dentron 160 XV Transverter** $199.95 ppd. USA
The Brand New 160-V Vertical Antenna

Another eye opener from Dentron, this new vertical antenna will solve your 160, 80 and 40 meter problems.

- Efficient Vertical Design
- Self Supporting
- Weatherproof
- Quick & easy one man installation
- Covers 160, 80 or 40 meter band with only one adjustment.

160-40V Antenna ............................ $79.50 ppd. USA

Here is another Dentron first, a six band antenna tuner designed to solve virtually any matching problem you may have.

- Covers all bands 160 through 10 meters
- Handles maximum legal power
- Matches coax feed, random wire and balanced line
- Includes heavy duty balun for balanced line
- Black wrinkle finish cabinet

160-10 Super Tuner .......................... $119.50 ppd. USA

This is the low cost way to match almost any random length wire on the five most used HF bands.

- Covers 80 through 10 meters
- Handles maximum legal power
- Matches random length long wire antennas
- Features Dentron quality and value

Model 80-10 Antenna Tuner .......................... $49.50 ppd. USA

Be ready for restructuring — Special Supertuner handles 3 KW PEP amplifiers —

$229.50 ppd. USA

loop antenna

receiving aid

A method for improving signal-to-noise ratio on the lower-frequency bands

You've heard it before and it's worth repeating: "If you can't hear 'em, you can't work 'em." Most hams I've talked to or heard on the air on the lower frequencies use quarter- or half-wave antennas in vertical, horizontal or inverted-vee configurations. While these antennas do a creditable job of transmitting rf, they can be noise collectors for receiving because of their physical size and proximity to man-made noise sources.

Presented here is a scheme that uses a fet preamp or a Q multiplier with a loop antenna which is easy to rotate from the operating position and will allow you to discriminate between signals and noise. The loop is only 18 inches (46cm) on a side with two windings spaced 2 inches (5cm) apart. A complete parts list and construction drawings are included. The loop structure can be made with a few pieces of wood, and the electronics are simple and inexpensive.

loop antennas

The rotary beam, if designed properly, discriminates well between the desired signal and interference. However, not many amateurs are fortunate enough to have a rotary beam for the lower amateur frequencies. If we sacrifice some gain and use a small loop that will give reasonable attenuation on an interfering signal or noise, we'll have a desirable receiving aid. Such an antenna has been around for years and its characteristics are well documented.1,2

Largely ignored by today's amateurs, the loop antenna was a standard piece of equipment in early ham stations but was generally huge and cumbersome because of the low frequencies in use in those days. The loop doesn't have to be large to be an effective noise discriminator on the lower amateur frequencies in use today. The entire assembly, including antenna and preamp or Q multiplier, can be mounted on your receiver. Used properly, this combination could mean the difference between solid reception and frustration.

Loops have a pattern that exhibits maximum response in the plane of the loop and minimum response in a plane normal to the loop (fig. 1). Note that
this response is exactly opposite to that of a quad antenna. This suggests that a small loop antenna with appropriate electronics might be useful as a noise discriminator on the higher amateur frequencies when used as a receiving aid with a quad.

**receiver input impedance**

A loop antenna with its tuning capacitor is a common LC circuit. It could be substituted for the tuned circuit in your receiver RF amplifier. Few hams, however, would want to make the circuit modifications. Most modern receivers use a low-impedance antenna input; and since the basic loop has a high impedance, we need a one-turn loop coupled to the large tuned loop to act as a low-impedance transformer to the receiver input. See fig. 2.

**design examples**

The first thought that might enter your mind when constructing a loop is to use the number of turns required for the lowest frequency desired, and provide taps in the winding for the higher frequencies, which is not an uncommon practice with coils. My experience using this means has proved that it is not practical. For some reason, the unused turns seem to saturate the loop, and a sharp resonance becomes hard to achieve. Also the directivity pattern becomes questionable. I've found that it's better to wind two separate loops on the same frame, with the most spacing you can provide between the two windings, e.g., about 2 inches (5cm) will provide excellent performance. I've also found that as far as the LC ratio is

fig. 1. Loop antenna field strength patterns.

fig. 2. High- and low-impedance loop outputs.
concerned, the higher the capacitance (within reason), the more effective the loop performance.

An example of this is the loop that I will describe. It is approximately 18 inches (46cm) on a side and contains two windings spaced 2 inches (5cm) apart. One winding consists of two turns spaced 1/4 inch (6.5mm) and covers 40 and 80 meters. The other winding consists of 5 turns spaced 1/4 inch (6.5mm) and covers 80, 160 and the high end of the broadcast band. With this arrangement, the loop is more effective on 80 meters using the 2-turn loop with high capacitance than the 5-turn loop with low capacitance.

fig. 3. Fet preamp for the loop antenna.

fig. 4. Loop antenna with Q-multiplier. Regeneration control is by means of L1, L3 coupling.

Loop with preamp input. While the loops performed satisfactorily in their basic configuration, as my first experiment I decided to add an rf amplifier using a solid-state device, and the circuit of fig. 3 evolved. Here the loop is connected to the gate of an HEP-802 fet and output to the receiver is taken from the source. Results were good, but I felt that the null could be improved, perhaps by increasing circuit Q.

Loop with Q-multiplier input. Recalling the principles of the Q multiplier, I decided to substitute such a circuit for the fet preamp (see fig. 4). Feedback control is obtained by an adjustable loop of wire, L3, coupled to the loop, L1. Receiver input is taken from L2. By rotating L3 within the field of L1 the desired amount of regeneration can be

The variable capacitor I use came from an old BC set. I wired its two stators in parallel and assume it has a maximum capacitance of 600 pF. I use a small dpdt switch to select the desired loop.
obtained, circuit Q is improved, and the null is much more pronounced. Better control is obtained for separating noise from the desired signal.

Note that a loop antenna can also be used as an absorption wavemeter. When using it with solid-state devices beware of placing the loop in a strong rf field.

**construction**

Fig. 5 and the parts list (table 1) should be self-explanatory. The basic loop contains two windings: a two-turn loop for 40 and 80 meters and a 5-turn loop for 80, 160 and the high end of the broadcast band. Four turns can be used if operation on the broadcast band is not desired.

The structural support for the loop wire is made from two strips of wood fashioned in a cross. The simplest winding is made by starting the wire from the outside, winding around and around, to the inside. The wire is supported on the cross arms with tacks or notches. The size of the frame, number of turns, and spacing will be determined by the desired frequency coverage.

Another winding pattern is made as a large, square-shaped, wide-spaced solenoid. In this case, short strips of wood are required at the appendage of the supporting arms, with notches to support the wire. Here again the size, number of turns, and spacing will depend on the frequency range desired.

Incidentally, there is a school of thought that reasons as follows: Since the maximum gain of a loop antenna is in the plane of the wires, a loop wound in a wide-spaced solenoid configuration and mounted in a diamond position (points of the square top and bottom) will have a better capture area. While I can’t prove it, I am inclined to agree.

Since the wire is the only important element of a loop, the basic construction of the frame can be left to your ingenuity and materials on hand. The frame, of course, should be made with insulating material. I suggest that the wood frame be painted with coil dope.

Fig. 6 details the loop wire support arms. Note that one extra notch for wire is required in the bottom arm due to the winding pattern. I formed the notches in the support arms in the following manner. I drilled the required number of holes in the arms on a line about 1/8 inch (3mm) in from the outside edge, then clamped the supports in a vise and cut slots into the holes with a hacksaw. Next I folded a piece of sandpaper and widened the slots to suit the wire size. A piece of string a little
From Corvus, a unique 100% solid-state digital clock packed with features any ham radio operator will appreciate.

Built around a single MOS integrated circuit, Zulu 10 provides 24-hour GMT with to-the-second accuracy. The special alarm alerts you every 10 minutes with a soft, pleasant signal to help you meet station identification requirements. And it's reset with a single "flick of the wrist" motion of the clock.

**Feature-packed, trouble-free operation.**
- Bright LED display for hours and minutes.
- Seconds are indicated by a pulsing lamp.
- Automatic display dimming for easy viewing.
- Attractive, compact silver case.
- Pushbutton controls neatly tucked in base.
- 60 HZ AC operation.
- Full year written warranty.

Designed and engineered for the ham radio operator by Corvus Corporation, Dallas-based subsidiary of Mostek Corporation, an industry leader in MOS integrated circuit technology.

Order yours today.

---

larger than the wire diameter, rubbed over a candle and worked into the slots, made it easy to obtain proper tension in the loops when securing the ends.

The feedback-loop support dowel should be cut 1/4 inch (6.5mm) shorter than the space between the supports. The ends of the dowels should be drilled on the vertical centerline to take a short length of heavy wire. This wire should project 3/8 inch (9.5mm) at the top and 1/8 inch (3mm) at the bottom. The supports should be drilled at their centerline to accept the wire. The dowel is inserted into the top support first, then swung in to the bottom support hole. Rotation to obtain proper feedback is by manual adjustment. In constructing the loop frame, I cut all pieces to proper length and shape, then assembled them using *Pliobond* cement and a few brads.

Fig. 7 is a suggested circuit to supply power to a loop antenna preamplifier through the coaxial transmission line when the loop is in a remote location. I suggest that the voltage drop that might occur in the two RF chokes be checked and, if warranted, the voltage increased.

Tilt-over tower uses extension ladder

Tilt-over tower based on the use of a 40-foot aluminum extension ladder is inexpensive and easy to erect. It is difficult to beat the tilt-over tower as a means of supporting your beam antenna as it permits easy access to the elements for adjustments or repairs. Unfortunately, these structures are expensive and require a rather elaborate installation. If you are required to move because of a job change, retirement, or just plain restlessness, there then arises the problem of what to do with the tower. Many times it must be either given away, or sold at a substantial loss.

The system described here makes use of a readily obtainable aluminum extension ladder which is light, easy to handle, and far less expensive than the usual tower. And if you should move, it is easier to transport or, if necessary, dispose of the ladder which can always be put back to the sort of work for which it was originally intended.

fig. 1. Top of tower is braced with wooden rung and tension cables. Rotator is mounted on side.
construction

After installation of this tower, the whole assembly is erected in the retracted position; the ladder is then extended to its full height for rigging. For my 15- and 10-meter quad an Alliance TV rotator with thrust bearing was mounted on the ladder as shown in fig. 1. To prevent twisting and damage to the ladder from wind action, a wooden rung was inserted at the extreme top of the upper section, with two crossed cables with turnbuckles for tensioning, as shown in fig. 1. Don’t mount your beam without this modification to the ladder.

The swiveled feet originally installed on the bottom of the ladder were removed by drilling out the rivets and reaming the holes to a diameter permitting the insertion of a length of half-inch (13mm) iron pipe (fig. 2). This pipe becomes the pivot which anchors the bottom of the tower.

The ladder is secured vertically against the end of the house by a lag bolt through a board fitted between the vertical members of the ladder’s lower section as shown in fig. 3. An eyebolt to the frame of the house secures a block and tackle which is used to raise and lower the assembly.

Guy wires are fastened to the ladder by running them through the hollow rungs, and attaching the end as shown in fig. 4. Thus, extreme or continued stresses will not tend to pull the ladder apart.

Ladders of this type are available in lengths up to 40 feet (12 meters). With the additional height provided by the 10-foot (3m) rotating topmast, which supports the quad, a total height of more than 45 feet (13.7m) can be obtained.

With this type of antenna support, as well as with more conventional towers, the problem of neighborhood children,
fig. 5. Extension-ladder tower can be child-proofed by adding plywood covers to each side of the ladder.

or your own for that matter, climbing it, with resulting danger of injury, is ever present. The ladder can easily be made "child proof" by using two pieces of outdoor plywood, one on each side of the lower section, so that the rungs are effectively covered up (fig. 5). A conventional tower can be protected in a like manner by proper location of plywood shields so that no hand-holds are present. Means of securing the shield will be left to the ingenuity of the builder. A hasp from one shield through the other, with a padlock, would seem to be an effective arrangement.

This installation has been in place for a year or so, and has been very easy to operate single-handedly, taking a little over an hour to bring down the antenna, make whatever adjustments are necessary and put it back into operation.

KEYBOARD AND ENCODER KIT

* 53 Keys
* ASC II Encoder
* For: Terminals
  TV Typewriters
  Calculators
  RTTY Displays
  CATV and more

More keys—more features and still the same price. Our KBD-2 comes with "Line Feed", "Cancel" and "Escape" functions for more convenient teletype and computer operation. Two user defined keys are connected to isolated output lines on the connector to allow use as "Here Is", or other such special functions.

Keyswitches are full typewriter travel and response type, arranged in a modified ANSI layout. Full length spacebar with equalizer. Keyswitches are mounted on a fiberglass circuit board. The encoder provides a standard ASC II output and includes a debouncer circuit. ASC II code includes shift and control functions with three user defined keys available. Keytops are first quality double-shot molded types for permanent good appearance. Gold plated contacts on keyswitches. NEW—no surplus parts. Typewriter style—NOT a modified keypunch board.

KDB-2 Kit..................................................$39.95 ppd

ham radio
improved log-periodic beams

Dear HR:

When I originally started designing and building fixed log-periodic wire beams, I cut the active elements to resonate near the center of the 20- or 40-meter bands. I later discovered that it was better to cut these elements for the low end of the desired band. In my article on feed systems for log-periodics in the October, 1974, issue of Ham Radio, the rear element (element 1) was shown to be 35 or 36 feet (10.7m to 11m) long for the 20-meter antennas, and 70 to 72 feet (21.3m to 21.9m) long for the 40-meter versions. In these log-periodics the active element (element 2) was 32 to 33 feet (9.8m to 10.1m) and 64 to 66 feet (19.5m to 20.1m), respectively, for the 20- and 40-meter antennas.

I have since found that the forward gain and front-to-back ratio at the low-frequency end is improved by making elements 1 and 2, respectively, 37 feet (11.3m) and 33.4 feet (10.2m) for the 20-meter antennas, and 74 and 66.8 feet (22.6m and 20.4m) long for 40 meters. The remaining elements will be proportionately longer.

When designing log-periodics from scratch (see article on page 14), I now use 13.9 MHz and 6.9 MHz, respectively, for the low cutoff frequency of 20- and 40-meter log-periodics. This results in improved performance at the low end while the midband and high-end performance remain the same.

When installing a log-periodic beam, be sure that the area in front of the beam is clear of obstructions or other antennas. If you position your standard dipole or test antenna too close to the front of your log-periodic, it may completely upset the pattern. This was called to my attention by Tony Mony, K4LD. He originally had a 7-MHz inverted-vee only 10 feet (3m) in front of his 7-MHz log-periodic (which showed no gain). When he removed the inverted vee, the log-periodic provided lower swr over the 7-MHz band as well as good forward gain.

Camden, South Carolina

remotely-controlled gamma match capacitor

Have you ever wished you could adjust that gamma-matching capacitor on your beam from the ground? Or risked your neck up on a tower to get that last couple of tenths of swr?

Here's a way to make that adjustment right in your shack while sitting down. Burstein-Applebee* has a surplus TV remote-control reversible motor for $3.95 (catalog number 18A1465) which has enough torque to do the job. The unit comes with a 10k pot with protrud-

*Burstein-Applebee, 3199 Mercier Street, St. Louis, Missouri 64111.
ing shaft for hand adjustment. I coupled this shaft to an E. F. Johnson 140-pF transmitting variable with an insulated flexible coupler, weatherproofed the whole thing in an aluminum box, and mounted it on the boom near the driven element. Since the Johnson capacitor has a double-ended shaft, a control knob can be added for hand adjustment if you insist. You need a small three-wire cable down to the shack for remote operation and Burstein-Applebee includes a schematic for the motor which operates on 115 volts, 60 Hz.

Since it's an instant start and stop device, with a little practice you can catch it at the bottom of the null. The 10k pot can also be used to work up a servo-control to operate a multi-position wafer switch for remote antenna switching. Disable the detent mechanism of the switch, though, as the motor doesn’t have enough torque to overcome it.

Forrest Gehrke, K2BT

antenna mast design

Dear HR:

The technique of antenna mast design discussed in my article “Design Data for Pipe Masts,” in the September, 1974, issue of ham radio is based on approximations accounting for the fact that pipe masts are highly flexible structures.

WB9DES recommends that such masts be designed by the technique of analysis used for rigid beams. This can be done using the curves of the article as follows:

1. Calculate the length of the top section as in the example.

2. Calculate the second section length in the same way, but treat this as a trial value. For a second trial, refer all upper loads to the top of the second section: From the curves determine the allowable section length, and use this as a second trial value. Repeat until the trial value and graph value agree.

3. Repeat the process of step 2 for each lower section until the desired height is obtained.

Masts designed by this method will deflect less under load, and will have a larger safety factor.

speech processing

Dear HR:

My attention has been called to G6XN’s article of speech processing in the November and December, 1972, issues of ham radio and the subsequent correspondence. I feel that there are still some points to be clarified, particularly in reference to audio clipping.

It is rightly supposed that audio clipping produces harmonic distortion products within the upper registers of the speech spectrum. The superiority of rf clipping comes from the fact that such products are largely eliminated. The unwanted distortion products can be regarded as noise and their existence constitutes a decrease in the signal-to-noise ratio, making it more difficult for the listener to perceive the essential speech components. Harmonic products are not, however, the only disturbances produced by audio clipping. Largely overlooked is a high-frequency mutilation effect. What happens is that on any extreme swings of the primary low-frequency components, any high-frequency ones get erased by the limiting action of the clipping diodes. This can be seen if one analyzes the result of the clipping of a compound waveform.
fig. 1. Speech clipping results in mutilation of the higher audio frequencies by the lower ones as shown here. VK4LR suggests a sub-band speech processing system to solve this problem (see text).

consisting of two components of about equal amplitude (see fig. 1A). Separating the two components after clipping (fig. 1B) illustrates that the high-frequency one has been reduced to modulated pulses. In other words, in the presence of a strong low-frequency component and with heavy clipping, any high-frequency component information can only be conveyed during and near the times of zero low-frequency component value. All high-frequency components thus become strongly mutilated. As the human voice relies for the most part on a number of simultaneously occurring frequency components, articulation is destroyed by this high-frequency mutilation as well as from the occurrence of harmonic products caused by wave squaring. While rf clipping eliminates the harmonic product problem it does little to cure the mutilation of higher frequency audio components.

One solution I am investigating is that of splitting the speech band into a number of sub-bands and treating these separately by clipping and filtering. The sub-bands are combined after processing to reconstitute the full speech spectrum. Thus, any harmonic products generated by the lowest sub-band, 350 to 700 Hz, are filtered off by a lowpass filter section set to cut off above 70 Hz. Since the first troublesome harmonic of the lowest possible frequency that can be passed is at 1050 Hz, it is well into the filter rejection region and can cause little offense. Providing several components of the speech waveform do not both fall into the same sub-band, no high-frequency mutilation can occur. Analysis of typical speech pattern shows that the formats generally fall roughly an octave or so apart. Thus simultaneous occurrences of two formats in the same sub-band would be infrequent.

Preliminary test of the multi-sub-band system indicates that very little change in speech quality results when the system is introduced to the circuit. No substantial data has been yet obtained as to the communication gain that might be had, but some reports indicate that the gain is considerable.

Queensland, Australia

**reciprocating detector**

Dear HR:

I built a reciprocating detector described by W1SNN* and found that the concept of locating the reference filter in the middle of the passband was not acceptable, at least for receivers with high selectivity. To use it, I incorporated another stage of conversion in my Collins 75A3, using the original bfo for beating so that the passband could be shifted in relation to a new reference filter crystal frequency of 80 kHz. With this addition and a circuit modification to make the feedback symmetrical, performance of the circuit has been very worthwhile.

D.H. Gieskieng, W6NLB
Rialto, California

Don't let the small size fool you. The spectacular Atlas transceiver is truly a Giant Killer. Just 7 pounds of sheer dynamite, it occupies only 0.18 cubic feet. But this is only a small part of the story. There are many other reasons why you will want to own an Atlas Transceiver:

MOST ADVANCED STATE-OF-THE ART CIRCUIT DESIGN, INTRODUCES A NEW ERA IN PERFORMANCE SPECS. We ask you to mark these words. They are not merely an advertising statement.

RELIABILITY: Total value engineering, craftsmanship and quality control give you unsurpassed reliability. With over 1000 Model 180's now on the air, we at Atlas are proud of their most exceptional reputation for performance, reliability, and owner satisfaction. It is safe to say that practically every owner has a love affair going with his Atlas radio. You too can have such an affair.

RECEIVER SENSITIVITY AND RESISTANCE TO OVERLOAD AND CROSSMODULATION, SECOND TO NONE. (Better than anything else we have seen or any other claims.)

SELECTIVITY: A breakthrough in filter design by Network Sciences. Designed specially for Atlas, this filter provides unprecedented selectivity. Only 9200 cycles wide at 120 db down when installed and measured in the Atlas transceiver! Ask any other brand for specs at this level! And to top this off, the front end design of the Atlas makes it possible to utilize this fantastic degree of selectivity!

TRANSMITTER TALK POWER: 200 watts of linear solid state power input, with clear, crisp audio.

NO TRANSMITTER TUNING: Simply connect to a 52 ohm load and you're on the air. Infinite SWR protected.

IDEAL MOBILE SIZE: One-third the size of any other 5 band HF transceiver. Only 3½ in. high, 9½ in. wide, 9½ in. deep.

PLUG-IN DESIGN provides quick removal from mobile mount. Plugs into AC console, as illustrated, giving you a handsome desktop station.

Model 210 covers 3700-4050; 7000-7350; 14,000-14,350; 21,100-21,450; 28,400-29,100 KHz.

Model 215 covers 1800-2000; 3700-4050; 7000-7350; 14,000-14,350; 21,000-21,450 KHz.

The new 210 and 215 are identical to the former Model 180 except for band coverage.

SPECIAL MARS MODELS, 210M/215M permit out of band operation when used with Model 10X external crystal oscillator accessory.

NOISE BLANKER, optional plug-in. Also VOX, and other accessories.

CUSTOMER SERVICE, second to none. Your satisfaction is guaranteed.

ALL THIS, and priced lower than any other 5 band solid state or hybrid transceiver.
unique method of clamping aluminum tubing

Have you ever tightened the U-bolts around a 1¼-inch (32mm) aluminum tube, only to have it slowly collapse as you torque up the nuts? To add to the frustration, the aluminum tube takes a permanent set which limits the amount of force the clamp can be made to apply.

The use of steel U-bolts to join tubing is common practice with commercial antenna installations. The U-bolts are simple and economical, but their use with aluminum tubing generally leads to the problem mentioned above. An alternative is to fabricate special clamps, such as those illustrated in the ARRL Handbook.¹ If minimizing weight on the mast is as important to you as it is to me, then the following description of a relatively simple fix, using commercial U-bolts, should be of interest.

Materials. The parts that are needed are easily made with a bench vise and a hacksaw. If a tube cutter is available, it can also be used to advantage. Parts to be fabricated are a half-section of 1¼-inch (32mm) steel tube about three inches (76mm) long, and two 7/16-inch (11mm) aluminum tubes just long enough to fit crosswise inside the 1¼-inch (32mm) tubing (about 1-1/8 inch [28.5mm] long). The latter should be a number-16 tube which has an inside diameter of 0.307 inch (8mm).²

Step-by-step procedure. First, using a hacksaw or tubing cutter, cut off a 3-inch (76mm) section of 1¼-inch (32mm) thinwall steel tube and drill a set of holes through it for the U-bolt.

![fig. 1. Mechanical parts required for clamping aluminum tubing without deforming it consist of two aluminum inserts and a steel half-section. Assembly of the parts is shown in fig. 2.](image)

(The open end of ¼-inch [6.5mm] steel clamps are generally 1-3/4 inch [44.5 mm] apart.) Second, place the tube crosswise in a vise. Using a hacksaw, cut it in half lengthwise, midway between the two sets of clamp holes. Remove the burrs with a file.

The third step is to cut two lengths of 7/16-inch (11-mm) aluminum tubing

approximately 1-1/8-inch (28.5mm) long, or just long enough to slip cross-wise inside the 1¼-inch (32mm) aluminum tube. The finished parts are illustrated in fig. 1.

Assembly. It is necessary to insert the two 7/16-inch (11mm) aluminum tubes inside the 1¼-inch (32mm) tubing to mate with the U-bolt holes. The inner tube can be positioned with the aid of long nosed pliers. To hold it in place temporarily, drop a ¼-inch (6.5mm) screw through the hole; then insert the other 7/16-inch (11mm) tube, holding it in a similar manner. The U-bolt can then be inserted from the bottom, pushing the screws out in the process. Before inserting the U-bolt fit one of the steel half-sections on the clamp as shown in the assembly diagram of fig. 2.

Using the clamp assembly. Fig. 3 shows a typical installation using the modified clamp assembly. Note that the aluminum inserts and the steel half-tube prevent the 1¼-inch (32mm) aluminum tubing from collapsing under the force of the U-bolt nuts, either in the vicinity of the clamp or at the junction between the two tubes.

Norman J. Foot, WA9HUV

open-wire feeder
feedthrough insulator

Open-wire feeders (ladder line or twinlead) should be kept clear of objects which might unbalance the rf currents on the line. Getting the line from indoors to outdoors can thus be a problem. A feedthrough system can be fashioned from about a foot (30cm) of scrap PVC tubing with end plates cut from a plastic bleach bottle (fig. 4). Run the line through the wall (a screened attic gable vent makes an easily prepared place) and through the tubing. Cut the end plates with tabs to fit the
tubing. Cut a slot in each plate, and enlarge it at the center so as not to severely bind the feeder. Slide the end plates over the feeder, and then into the ends of the tube.

Although the tabs provide enough tension to hold the plates in place, epoxy or PVC glue will insure they stay put. When the glue is set, slide the tube into the wall hole. You may want to paint the tube to match the house exterior. Adjust the feeder so that it runs through the center of the tube. A drop or two of epoxy will hold it in place.

Seal the point where the pipe passes through the wall. If the tube passes through screening, hangers can be fashioned from the same bleach bottle used for the end plates. The end plates do double duty by also keeping bugs and squirrels from getting indoors.

L.B. Cebik, W4RNL

dielectric antenna for 10 GHz

Above 1296 MHz it is impractical to use conventional antennas such as simple dipole arrays, Yagis and collinears. Instead, a different class of antennas is found: reflectors (both cylinders and parabolas) and horns. One antenna type which has seen relatively little amateur application is the dielectric rod antenna, probably because few military and commercial stations use them, and secondly, because their design is largely empirical. Finally, the construction of required tapered dielectric sections is beyond most amateur workshop capabilities.

The antenna described in this article, however, can be easily built by the amateur, and consists of a tapered dielectric slab inserted directly into the waveguide. Amateurs using coaxial systems can merely use a coax-to-waveguide adapter. As can be seen in fig. 5, the taper is not smooth, but varies in abrupt jumps every 5cm (2 inches) along the antenna, which is easier to construct. Inside the waveguide, the jumps are every 2cm (3/4 inch). These dimensions are not critical (±0.5cm or ±3/16 inch) but the increments should be uniform. The taper inside the guide matches the impedance of the antenna to the impedance of the waveguide.

The antenna is constructed by laminating strips of 1/10-inch (2.5mm) thick plexiglass window glazing with a solvent

Dielectric antenna for 10 GHz uses laminated strips of 0.1" (2.5mm) plexiglass window glazing. Gain is about 14.5 dB above an isotropic radiator and is flat across the 3cm amateur band.

such as ethylene dichloride. This thickness is chosen because four layers closely match the inside height of the commonly used WR-90 waveguide. All of the strips are 0.9 inch (23mm) wide. The result is a tapered dielectric plug which slides easily into the waveguide. The plug can be secured in the guide with either non-conducting epoxy cement or nylon screws.

A word of caution if you use screws. First, they must not be conductive and second, they should be mounted along the centerline of the wide dimension of the waveguide; otherwise the resultant holes will couple power out of the guide, resulting in lower gain and higher side lobes.

The completed dielectric antenna exhibits a gain of 10 dB above an open-ended section of waveguide or about 14.5 dB above an isotropic radiator, and gain is flat across the 3cm band. The horizontal and vertical radiation patterns are plotted in fig. 6. The vertical beamwidth is 25° whereas the horizontal beamwidth is about 20°.

John M. Franke, WA4WDL

cornell-dubilier
ham rotators

Cornell-Dubilier Electronics* has confirmed that the Ham-M and the Ham-II rotators, and also the control units, are interchangeable. Therefore, stand-by spare rotators of either kind can be used with either control unit. Furthermore, all rotator parts have the same stock numbers and internal photographs, so spare parts can be kept on hand and used in either rotator.

In addition to the convenient calibration switch, the addition of a 180-ohm resistor and a 13-volt zener regulator to the Ham-II is a welcome change as it holds the calibration constant under conditions of varying line voltage.

The possibility of burning out the direction indicator potentiometer can be eliminated by placing fuses between the potentiometer and terminal screws 3 and 7, inside the rotator.

Bill Conklin, K6KA

*Cornell Dubilier Electronics, Department C, 118 East Jones Street, Fuquay-Varina, North Carolina 27526.
High-Q Beam Antennas

Heavy duty 4-element Tribander
Four working elements on each band in 10, 15 and 20 meters. 24 foot boom permits optimum spacing for maximum forward gain and front-to-back ratio. All traps are precision tuned and weather-proofed. Rugged reliability assures ability to withstand winds up to 100 mph. TB-4HA. $249.95

Economical 2-element Tribander
Two working elements on each band in 10, 15 and 20 meters. 6.5 foot aluminum boom can easily be raised on an inexpensive mast and operated with a standard TV rotator. Withstands winds up to 80 mph. TB-2A. $129.95

Heavy duty 3-element Tribander
Three working elements on each band in 10, 15 and 20 meters. 16 foot boom requires a lighter duty rotor and tower than the TB-4HA but still provides excellent performance characteristics. Precision tuned and weather-proofed traps are combined with rugged construction. TB-3HA. $189.95

Heavy duty 2-element 40-meter Beam
Two working elements on 15.75 foot steel boom. Maximum forward gain and front-to-back ratio in the CW or phone portion of the 40-meter band is easily achieved for optimum performance. Large high-Q loading coils are weather-proofed. Rugged design easily takes 100 mph winds. MB-40H. $199.95

All Swan Beam Antennas are Rated for 2000 Watts and designed to use 52 Ohm coaxial feedlines.

antenna circuit indicator

A new automatic indicating device designed to warn vhf communications equipment operators of antenna problems has been announced by Ascom Electronic Products, a division of The Antenna Specialists Company. Recognizing the fact that mobile communications antennas are often subjected to some degree of damage, and that the problem is usually not immediately detected by the operator, the antenna circuit indicator immediately alerts the operator to a problem. It also helps prevent damage to equipment by eliminating long periods of transmission into extremely high vswr. The indicator, model ASM-104, is an especially valuable device where maintenance of communications is critical.

The new Ascom antenna circuit indicator is designed for easy mounting under the vehicle dash. Two lights are used to give the operator instant indication of the system's operation. When transmitting, one light indicates the normal condition of rf power being transmitted. Should the second indicator light, showing reflected rf power, it alerts the operator to antenna problems that could affect communications capability. For reliability, LEDs are used for indicators, eliminating bulb burn-out problems. The unit uses no batteries or connection to other power sources, requires only 10 watts or more of rf energy, and operates over a frequency range of 144 to 174 MHz. Complete details on the new ASM-104 indicator are available from Ascom Electronic Products, 12435 Euclid Avenue, Cleveland, Ohio 44106, or by using check-off on page 126.

aluminum towers

A new line of fully-assembled, crank-up aluminum communications masts in 40 to 60 foot heights, and prefabricated towers up to 100 feet, has been announced by Fred Franke, Inc. The maintenance-free Aluma Towers are available in a variety of heights and designs for ham radio and commercial and industrial communications systems. The 40-foot tower weighs 56 pounds and the 60-foot model weighs only 95 pounds. Both include the crank-up feature.

The corporation will also manufacture a fixed-guy tower using 10- or 20-foot sections up to a total of 100 feet. The first 50 feet can be assembled on the ground with the remaining units added with special pre-drilled sleeves. The weight of a 10-foot add-on section is only 15 pounds. A special non-guyed tower for mobile homes will also be available. This unit will include a 20-foot high triangular base with a 10-foot extension for a total of 30 feet. The crank-up models, all heliarc welded, are
antenna magnetic mount

Using a new type of permanent magnet in a configuration that achieves maximum magnetic pull, Larsen Antennas has just introduced a mobile antenna that has an amazing ability to "stay put." In fact, the hold is so strong that caution must be exercised when placing the mount to be sure you get it where you really want it.

The Larsen Magnetic Mount is available in five different models which accommodate all popular types of mobile antennas including Motorola, GE, DB Products, Antenna Specialists, and, of course, all Larsen Models. The unit comes complete with 12 feet of RG-58A/U coax and plug all attached. All that is needed to become operational is to screw the antenna into the base, place the magnetic base on the vehicle roof, fender, trunk or any other convenient spot and run the attached coax to the equipment.

The magnet used on the Larsen mount is guaranteed to be permanent and to stay in place on the vehicle (a flat surface is required) at any highway speed. Design of the mount is such that full capacitance coupling assures adequate ground plane for full antenna efficiency. For more details, write to Larsen Antennas, Post Office Box 1866, Vancouver, Washington 98663, or use check-off on page 126.
A new programmable scientific pocket calculator with significantly more keyboard functions and addressable memories than any previous pocket model was recently introduced by Hewlett-Packard. The new HP-55 is also the first pocket calculator with a built-in digital timer, valuable for short, timed experiments.

The nine-ounce HP-55 features simplified, keystroke programming, with 49 steps of program memory plus branching, testing and editing capability; twenty addressable memories, twice as many as any other pocket model; a total of 86 keyboard functions, operations and conversions; plus a digital timer with 100-hour capacity and the ability to store and recall as many as 10 splits (elapsed time readings within an event). Price of the HP-55 is $395.00 (domestic USA).

Like other HP pocket calculators, the HP-55 features the RPN (Reverse Polish Notation) logic system with a four-memory stack that holds intermediate answers and automatically brings them back when needed in a calculation. Beyond the standard arithmetic, trigonometric and logarithmic functions (including antilog), the HP-55 will work in any of the three trigonometric modes —
degrees, radians and grads — and allows the user to convert among any of them. The direct polar/rectangular conversion also enables the user to perform vector arithmetic.

The 20 addressable memory registers in the new calculator permit register arithmetic (with 10 memories) and simultaneous two-dimensional vector accumulation. The statistical functions of the HP-55, coupled with the 20 addressable memories, give the user the ability to do two-variable mean and standard deviation, linear regression and linear estimate, curve plotting and four simultaneous linear equations with four unknowns.

The direct conversions on the HP-55, which work both ways, include inches/millimeters, feet/meters, US gallons/liters, pounds mass/kilograms, pounds force/ Newtons, degrees fahrenheit/degrees centigrade, and BTU/Joules. Additional capabilities include percentage, root extraction, n factorial (for permutations and combinations), squaring numbers, raising numbers to powers and calculating reciprocals. The constant pi also is included.

HP has added a quartz crystal to the HP-55 circuit to provide a 100-hour timer accurate to ±0.01 percent. In the timer mode, the calculator display shows hours, minutes, seconds, tenths and hundredths. While the timer is running, the user can take and store up to 10 splits simply by pushing the digit keys. After the timer is stopped the splits may be recalled by pressing the appropriate digit key.

The HP-55 can display up to ten significant digits with a two-digit exponent and appropriate signs, and comes with an owner's handbook, quick reference guide, program notation pad and an ac adapter/recharger that allows the calculator to be operated on ac while its batteries are recharging. The HP-55, like other HP pocket calculators, will be sold through HP's calculator sales force, by direct mail and through leading college
Restructuring is coming!
Get that license now!

Let the experienced staff from the Glade Valley School Radio Session help you solve that license problem. Whether you are looking for your General, Advanced or Amateur Extra ticket they will help you in every way with their carefully prepared program to get the license you are looking for.

Have a “Vacation with a Purpose” at this beautiful location in the Blue Ridge Mountains. A highly qualified staff and excellent facilities combine to make license study a pleasant memorable experience.

bookstores and department stores.

Two handbooks containing programs for the HP-55 programmable scientific pocket calculator are also available. The $10.00 books, “HP-55 Mathematics Programs” and “HP-55 Statistics Programs,” contain general descriptions of the programs, formulas used in each program solution, numerical examples, user instructions, program listings and register allocations.

For more information, use check-off on page 126, or write to Inquiries Manager, Hewlett-Packard Company, 1501 Page Mill Road, Palo Alto, California 94304.

precision balanced mixer

Lithic Systems has announced a precision balanced mixer IC, types LS1596A and LS1596B, which are plug-in replacements for the popular 1596 balanced mixer. The frequency range of the new LS1596A/B has been increased to 250 MHz, and its guaranteed matching characteristics permit untrimmed operation with precision loads and sources. Applications include balanced modulation and demodulation, frequency heterodyning and multiplication, multiplexing and demultiplexing, and phase detection in ssb, dsb, a-m, fm and audio communications systems.

The LS1596A and LS1596B are available in 10-pin TO-100 packages. The LS1596B guarantees 1% internal matching while the LS1596A is specified at 2%. For more information, write to Robert A. Hirschfeld, Lithic Systems, Inc., Post Office Box 478, Saratoga, California 95070, or use check-off on page 126.

volt-ohmmeter

A skillful blending of features, quality parts and performance at an attractive low price may make the new RCA WV-547A volt-ohm-milliammeter the best selling general-purpose test instrument
in the electronic servicing field, according to RCA Electronic Instrument officials. Features that are not normally found in any VOM test instrument selling under $50 are included in the new RCA Tech VOM which is priced at only $19.95. These features include a no-stick taut-band diode-protected meter, dual detent function switch for long life, a rugged high-impact plastic case, accuracies of ±3 percent dc, ±4 percent ac with 20,000 ohms-per-volt dc sensitivity, and five functions with one percent precision resistors on all 19 ranges.

Designed for general purpose testing and servicing applications, the new RCA Tech VOM comes complete with test leads. An optional carrying case (WG-447A) is available for $5.75. Additional information on the RCA WV-547A is available from RCA Electronic Instrument Distributors, from RCA Electronic Instruments, 415 South Fifth Street, Harrison, New Jersey 07029, or by using check-off on page 126.

**Visual Display Unit**

HAL Communications Corporation has announced their new RVD-1005 visual display unit, the second generation version of the HAL RVD-1002, the first visual display unit offered to the teletype operator. The features that have made the RVD-1002 so popular are retained in the RVD-1005, and some new features have been added. For example, the RVD-1005 offers operation at 60, 66, 75 and 100 wpm, manual line feed and letters shift controls, se-

less Telegraphy, Edited by Sir Eric Eastwood, traces the development of telecommunications from the 1850s, when the submarine telegraph and Atlantic cable were first discussed. Attention turned to telephony in the 1870s, and then to “Signalling through Space Without Wires,” a famous lecture by William Henry Preece in 1897. From 1900 on the lectures were devoted to the development of wireless telegraphy, radio telephony and microwaves.

Marconi was a member of the Royal Institution and a frequent contributor to its famous series of Friday night discourses. Many of his lectures are contained in this book including “Wireless Telegraphy” (1900), “Transatlantic Wireless Telegraphy” (1908), and “Radio Communications by Means of Very Short Waves” (1932). John Ambrose Fleming, most famous for his invention of the diode detector, lectured on developments in radio communications and thermionic vacuum tubes.

Amateurs who are interested in the history of telecommunications will find this series of twenty-two lectures, given over a period of seventy-five years, to be both entertaining and educational. 391 pages, hardbound, $32.50 from Halstead Press, 605 Third Avenue, New York, New York 10016.

programmable operational amplifier

A new programmable operational amplifier which permits tailoring the electrical parameters to the user’s needs has been introduced by Motorola Semiconductor. Programming is achieved by a choice of an external resistor value of a current source applied to the I_{set} input. This allows optimization of dc characteristics such as input current, power consumption and bias current, and ac characteristics such as open-loop voltage gain, slew rate and gain-
break through the pile-ups!

it's the speech processor

and built-in sidetone with speaker. Powered by either 117 Vac or an inexpensive 9-volt battery, transistor output switching keys up to plus or minus 300 Vdc at 200 mA maximum. Key debouncing circuitry assures trouble free operation on any type of key paddle regardless of the condition of the contacts.

Housed in a low profile, two-tone blue metal cabinet weighing only 26 ounces, the EK-430 is priced at $124.95 fob the factory. For further information, write to Curtis Electro Devices, Inc., Box 4090, Mountain View, California 94040, or use check-off on page 126.

linear ic principles, experiments and projects

This new book by Ed Noll, W3FQJ, was written to introduce the principles of operation of the integrated circuit. Chapter 1 covers basic semiconductor principles: basic IC structures, the pn junction, the bipolar transistor, transistor fabrication and the field-effect transistor (FET). Succeeding chapters explain integrated-circuit structures, basic circuits, operational amplifiers, multipurpose and special ICs. The last four chapters give a broad coverage of how linear ICs are used in commercial, industrial and test equipment. Home-entertainment audio, a-m, fm and television applications are also stressed. Amateur radio and shortwave enthusiasts will find the projects in Chapters 9 and 10 good examples of the many opportunities for the use of ICs in the two-way radio field. These final chapters also will be appreciated by those who like the learn-by-doing approach; they’ll find an intriguing collection of school, lab and home construction projects. 384 pages, softbound, $8.95 from Ham Radio Books, Greenville, New Hampshire 03048.

audio sweep generator and frequency meter model 140B

The model 140B is virtually three instruments in one: an audio oscillator, audio sweep generator and frequency meter. It may be operated manually as a conventional oscillator, or swept automatically as a voltage-controlled generator. The generator sweeps over two ranges: a high range from 1 kHz to 20 kHz, and a special expanded low range from 40 Hz to 1 kHz, which allows for a close look at low-end frequency-response problems.

The frequency meter may be used independently. However, when connected to the output of the sweep generator the frequency reading is continuously displayed. Unlike digital counters, which are limited to measuring fixed frequencies, this frequency meter may be used to monitor the changing frequency of the sweep generator or any other external frequency source.

The model 140B is an excellent input source for testing amplifier frequency response, speaker enclosures and tape recorder head alignment. This low cost instrument provides a sine wave output that is variable from 0 to 2.5 volts p-p. Once set, the amplitude remains flat over the entire frequency range. (±1% dB) sine wave distortion is less than 1.5%. Square wave output is fixed at 8 volts p-p. $78.95 from Production Devices, 7857 Raytheon Road, San Diego, California 92111. For more information, use check-off on page 126.
semiconductor cross reference

The new edition of the semiconductor cross reference and transistor data book is now available from International Rectifier Corporation. The 70-page brochure lists over 44,000 parts and corresponding IR replacements including rectifiers, diodes, zeners, transistors, SCRs and ICs. All are indexed in straight alpha-numeric sequence to facilitate location of the desired part number. Also included are four pages of transistor specifications, showing polarity, case style, maximum current and typical bandwidth and gain. A data sheet on IC replacements lists absolute maximum rating and case style.

To obtain a copy of the cross reference (JD601), write Semiconductor Division, International Rectifier Corporation, 233 Kansas Street, El Segundo, California 90245 or use check-off on page 126.

ferrite-core kit

A sample kit containing 18 nickel-zinc and new high permeability manganese-zinc ferrites for winding wideband transformers including baluns can be obtained for $10.00 from the Fair-Rite Corporation. These cores are useful over a wide frequency range but were selected for their effectiveness at frequencies above 2 MHz. Applications include radio communications, vhf receivers, mobile communications and

NEW! NEW! NEW!
DELUXE P.C. KEYER

The complete P. C. keyer you can’t afford not to buy!

In either a 5 volt TTL or a 9 volt C-MOS version this new module type IC keyer can be easily adapted to your own custom package or equipment.

Versatile controls allow wide character weight variation, speeds from 5 to 50 w.p.m. plus volume and tone control.

Solid-state output switching saves power, eliminates all those annoying relay problems and is compatible with both grid block and solid-state circuitry.

With its side-tone monitor and 90 day warranty the Data Signal PC Keyer is the one for you.

TTL Keyer Wired $19.95 Kit $14.95
C-MOS Keyer Wired $24.95 Kit $19.95

Other systems operating at high frequencies.

The 18 ferrite core shapes are provided in three different materials along with application data including curves of parallel impedance, reactance and resistance per turn of wire for each sample core. Data also describes how to choose the right material and core size for a particular application.

Application data is available without charge. The sample kit can be ordered by sending a check or purchase order for $10.00 to Fair-Rite Corporation, Wallkill, New York 12589. For more information, use check-off on page 126.

sweep/function generator

A new low-cost sweep/function generator oscillator has been introduced by Exact Electronics. The model 195, priced at $149.50, is expected to make inroads into audio testing and amateur electronics applications where high performance function generators were not previously available. The new instrument, housed in a compact, rugged case, produces sine, square, triangle and swept waveforms as well as fixed amplitude pulses. Its frequency range is from 2 Hz to 200 kHz in three ranges with a linear/logarithmic frequency control.

An internal sweep generator will sweep 1000:1 (3 decades) on any of the three main frequency ranges. This permits technicians to sweep, either linearly or logarithmically, the entire audio range of amplifiers or speakers without changing ranges or even turning a knob. High and low level sine outputs with
amplitude control of both are provided. A voltage control frequency (VCF) input permits controlling frequency from an external source. Fully portable, the model 195 is powered by a 9-volt transistor battery, completely eliminating any problems with 60-Hz hum. An optional rechargeable power supply is available.

For more information, write to Exact Electronics, Box 160, Hillsboro, Oregon 97123, or use check-off on page 126.

solder slide rule
A handy new slide rule published by Kester Solder provides comprehensive flux selector data on one side and offers solder alloys guides on its flip-side. The pocket size Kester slide rule gives flux choices for 22 metals, ranging from easy-to-solder gold, copper, and tin to very-difficult-to-solder chromium and stainless steel. Thirty-six solder alloys also are listed, along with temperatures at which the solder becomes plastic and becomes liquid. Readers may obtain this slide rule by writing to Kester Solder, 4201 Wrightwood Avenue, Chicago, Illinois, 60639, Attn: Mack Haraburd.

touch-tone decoder board
A new seven-digit Touch-Tone Decoder board kit with multiple capabilities has been announced by CTI Manufacturing Company. The new board features full seven-digit Touch-Tone decoding and encoding, uses cmos circuitry, and is installed on a miniature 2¼ x 3¼-inch (57 x 82mm) circuit board. The board can be mated with an optional Touch-Tone pad, if desired, or used with existing equipment. The basic kit for the decoder board is priced at $59.50. For more information, write to CTI Manufacturing Co., Post Office Box 1422, Corinth, Mississippi 38834, or use check-off on page 126.
DATA SIGNAL SCORES AGAIN
NOW WELL ESTABLISHED IN THEIR NEW FACILITIES THE SUCCESSORS TO DATA ENGINEERING ARE LEADING OFF WITH BOTH EXCITING NEW PRODUCTS AND TIME PROVEN FAVORITES. YOU CAN DEPEND ON DATA SIGNAL FOR THE FINEST IN AMATEUR RADIO ACCESSORIES.

AUTOMATIC TOUCH TONE DIALER
Now, by the push of a single button you can automatically dial up to six separate 7-digit telephone numbers. All solid state with automatic PTT operation. Can send telephone number only, or repeater access code plus telephone number automatically.

AD6 Sh. Wt. 2 lbs. without keyboard 99.50
AMD-6 Sh. Wt. 2 lbs. with keyboard 119.50
Factory programming of #s 7.50

DELUXE REPEATER AUTO PATCH
The auto-patch your club will be proud to own. It's complete in every aspect. Two 1-4 digit access codes, one 1-4 digit disconnect, rotary dial or regenerated Touch Tone output, dial-in capability, "1", "0" and numerical disconnects, ID by-pass, audio monitor, keyboard, digital readout, plus many more features. Send for brochure. Rack mount only.

RAP-101 Sh. Wt. 15 lbs. 549.00

TOUCH TONE REGENERATOR
Give your Auto Patch users and the telephone exchange a break. Now all touch tone digits received by the telephone exchange is from ONE touch tone standard and not from a multitude of individual pads. Regeneration eliminates miss-dials caused by pads with off-frequency tones, incorrect amplitude adjustments, improper tone length, split tone bursts, etc. Includes complete 16-digit decoder plus rotary dial capability. PC board and rack mounting available.

DCR-71 PC 249.00 Rack 325.00
Sh. Wt. 2 lbs. Sh. Wt. 8 lbs.

REPEATER AUTO PATCH
It's complete — a single digit access/disconnect Auto Patch facility. All you need is a repeater and the phone line. Complete with automatic disconnect, dial-in capability, two way audio monitor plus remote control. When used with a rotary dial exchange, Data Signal's DPC-121 dial converter is also required. P.C. board or Rack Mount available.

RAP-2 PC 99.50 Rack 149.50
Sh. Wt. 2 lbs. Sh. Wt. 8 lbs.
TOUCH TONE TO DIAL PULSE CONVERTER

Don't let the lack of a Touch Tone telephone exchange prevent your repeater club from going auto-patch. Convert 0-9 TT digits to Bell System compatible dial pulse code. Uses anti-falsing TT decoder, 64-digit memory and solid state pulsing. Starts dialing on first incoming digit. Memory will not overload. Cancel function, * and # output provided for control purposes. PC Board and rack mount available.

DPC-121 PC 195.00 Rack 285.00 
Sh. Wt. 2 lbs. Sh. Wt. 10 lbs.

TOUCH TONE KEYBOARD/ENCODER

The smallest, thinnest keyboard with built-in touch tone encoder. Only ¼" thick. Completely self-contained, designed for mounting directly to hand-held portables. Operating temperature -20°F to +150°F. R. F. proof.

DT-4M Miniature Encoder 2¼" x 3" x ¾" 89.95 
Sh. Wt. 1 lb.

TOUCH TONE PADS

Standard size 12 and 16 digit Touch Tone Pads. Automatic PTT operation with 1½ second transmitter hold. Self powered via internal 9V battery. Audio and PTT outputs, TTP-1 and TTP-2 also has low volume audio monitor for acoustically coupling of tones to microphone. Zero quiescent current. Operating temperature -20°F to +150°F. R. F. proof.

TTP-1 16 digit 3" x 5½" x 1½". Sh. Wt. 2 lbs. 79.50
TTP-2 12 digit 3" x 5½" x 1½". Sh. Wt. 2 lbs. 59.50
TTP-3 12 digit 2¼" x 4¼" x 1½" Sh. Wt. 2 lbs. 59.50

ANTI-FALSING TOUCH TONE DECODER

Now, a true anti-falsing decoder, immune to high noise and voice falsing. 12 to 16 digit capability. Single 5-volt power supply. Heavy duty transistor output. Complete p. c. board or standard 19" rack available.

TTD-126-12 12 digit PC 149.95 Rack 219.95 
TTD-126-16 16 digit PC 169.95 Rack 239.95 
Sh. Wt. 2 lbs. Sh. Wt. 10 lbs.

WILSON 204 MONOBANDER

Low Low Prices

The Wilson 204 is the best and most economical antenna of its type on the market. Four elements on a 26' boom with Gamma Match (No balun required) make for high performance on CW & phone across the entire 20 meter band.

The 204 Monobander is built rugged at the high stress points yet using taper swaged slotted tubing permits larger diameter tubing where it counts, for maximum strength with minimum wind loading. Wind load 99.8 lbs. at 80 MPH. Surface area 3.9 sq. ft., Weight 50 lbs., Boom 2” OD.

All Wilson Monoband and Duoband beams have the following common features:
* Taper Swaged Tubing
* Full Compression Clamps
* No Holes Drilled in Elements
* 2” or 3” Aluminum Booms
* Adjustable Gamma Match 52 $2
* Quality Aluminum
* Handle 4kw
* Heavy Extruded Element to Boom Mounts

- M204 4 ele. 20, 26', 2” OD $119.95  
- M203 3 ele. 20, 20', 2” OD $ 89.95  
- M155 5 ele. 15, 26', 2” OD $119.95  
- M154 4 ele. 15, 20', 2” OD $  79.00  
- M105 5 ele. 10, 20', 2” OD $ 69.00  
- M106 6 ele. 10, 26', 2” OD $ 89.00  
- M104 4 ele. 10, 17', 2” OD $ 49.00  
- M340 3 ele. 40, 40', 3” OD $349.00  
- M240 2 ele. 40, 16', 3” OD $199.00  
- M520 5 ele. 20, 40', 3” OD $189.00  
- M715 7 ele. 15, 40', 3” OD $159.00  
- DB45 4 ele. 15, 5 ele. 10, 26', 2” OD $129.95  
- DB43 4 ele. 15, 3 ele. 10, 20', 2” OD $ 99.00  
- DB54 5 ele. 20, 4 ele. 15, 40', 3” OD $209.00

All Wilson Antennas are FACTORY DIRECT ONLY! The new low prices are possible by eliminating the dealer’s discount. All antennas in stock. If you order any antenna you may purchase a CDR Ham II for $124.95 or a CDR CD44 for $84.95. Send check or money order, or phone in BankAmericard or Master Charge. All 2” Boom antennas shipped UPS or PP, 3” by truck.

SUPER CW FILTER

The IMPROVED CWF-2BX offers RAZOR SHARP SELECTIVITY with its 80 Hz bandwidth and extremely steep sided skirts. Even the weakest signal stands out. Plugs into any receiver or transceiver. Drives phones or connect and speaker. Design uses one octave from center frequency to 60 WPM. MFJ Enterprises, P.O. Box 494, Miss. State, MS 39762, (601) 323-5869.

Feature for feature the CMOS-ELECTRONIC KEYER gives the most for your money: State of the art design uses digital CMOS ICs and NE555 sidetone • Built-in key with adjustable contact travel • Sidetone and speaker • Adjustable tone and volume. For external key. 4 position switch for TUNE, OFF, ON. SIDETONE OFF. Two output jacks: direct relay, grid block keying • Uses 4 penlight cells (not included). Self completing dots and dashes. Jam proof spacing. Instant start with keyed time base. Perfect 3 to 1 dash to dot ratio. 6 to 60 WPM. Relay rated 250 VDC. 1½ amp, 30 VA. CMOS-440RS, Deluxe ... $37.95.

Write for FREE catalog and CW filter test reports. Please include $1.50 per unit for shipping and handling. Money back if not satisfied. One year UNCONDITIONAL guarantee.

MFJ Enterprises, P. O. Box 494, Miss. State, MS 39762, (601) 323-5869

THE DELA-BRIDGE I

Analyses antenna characteristics, simplifies adjustment.

The DELA-BRIDGE I, when tied into your grid dip meter or low power exciter, quickly and easily analyzes: (1) Existing antenna & feed line characteristics, (2) Tuning & loading coils, (3) Filter & interstage coupling networks. Direct readout then lets you adjust for optimum performance.

DELA-BRIDGE I Specifications:

- FREQUENCY RANGE: 50 KHz to 250 Mhz
- RESISTANCE RANGE: 0 to 500 Ohms, balanced or unbalanced, log scale
- SIGNAL REQUIREMENTS: 1 MW to 2 Watts maximum from any grid dipper or signal generator
- POWER REQUIREMENTS: Internal 9V battery
- ACCURACY: ±3% at 50 Ohms
- TO READ & INTERPRET: Complete null and reactance determination—not frequency sensitive—internal integrated circuit amplifier allows use with low signal inputs

DELA-BRIDGE I guaranteed for 1 year by Delavan Electronics, Inc.*

Delavan Electronics' new Amateur Products Group might be a new name to you, but we're no stranger to amateur radio operations and equipment. Delavan is well funded and deeply involved in aerospace and industrial controls. Delavan stands behind its products 100% and guarantees the DELA-BRIDGE I unconditionally for 1 full year. Order your DELA-BRIDGE I today!

Problem . . . . . Your local club has decided to put up a repeater, but funds are limited and you know that an old commercial tube rig converted will work but never will be first rate.

Solution . . . . “The Life Saver” — A state of the art completely solid state repeater. Complete including CW-ID, control circuitry, power supply (12V 12Amp) and all hardware. Packaged to take up to 25,000 microvolts before desensing.

PRICES

Kit $364.95  Factory wired and tested $595.00

Need Cavaties? With kit or wired and tested repeater, add $399.95 for commercial grade 6 cavity system.

"THE LIFE SAVER"
SAROC HAWAIIAN HOLIDAY
including
SAROC’s First Hawaiian Convention

Spend 8 fabulous days in exciting Hawaii

HERE ARE SOME REAL GOODIES AT DOWN TO EARTH PRICES. QUANTITIES ON SOME ITEMS ARE LIMITED . . . IF YOU SEE SOMETHING YOU LIKE DON'T DELAY . . . ORDER NOW.

--- SOLID STATE RECEIVER STRIPS ---
WE HAVE JUST GOTTEN IN SOME CLEAN GENERAL ELECTRIC MASTER PRO HI BAND RECEIVER STRIPS. THESE STRIPS ARE SOLID STATE AND IDEAL FOR REPEATER USE OR JUST PLAIN MONITORING . . . CHECK THESE FEATURES . . .
136-150 MHz Range  2 Freq Narrow Band

ONLY $100.00 ea.

--- SOLID STATE TRANSMIT STRIPS ---
WE HAVE A LIMITED QUANTITY OF TRANSMIT DECKS FROM THE HI BAND GENERAL ELECTRIC PORTA MOBILE UNITS. THEY ARE EXCEPTIONALLY CLEAN. 136-150MHz RANGE, CAPABLE OF PROX 6 WATTS OUTPUT. EXCELLENT EXCITERS FOR FM OR CONVERSION TO USE ON OSCAR.

ONLY $49.00 ea.

--- MOTOROLA GOODIES ---
ATTENTION REMOTE BASE OPERATORS
Here are some special T-Power mobiles just for you. They are Motorola X43BGT type units. They are 2 freq transmit 150 MHz and 2 freq, PL* dual squelch, narrow band receive on 450. Ideal for use with your remote base. Less accs.

IF YOU DON'T NEED THE WHOLE RADIO HERE ARE SOME STRIPS

UHF “B” RECEIVERS
These are the 2 freq, PL* dual squelch, narrow band receivers from the X43BGT. They are the same size as a hi band “G” strip. Ideal for link receivers

$39.00

T-SUPPLIES
From the X43BGT. Unit comes with the supply, and heatsink. Can be converted for use with your T41 or T43 radio. Here's your chance to update your vibrator rig

$25.00

$10.00

30 WATT HI BAND TRANSMIT STRIPS
Motorola “G” series transmit strips. No weird tubes. Uses 6146 final. Ideal for FM or can be converted for use as an OSCAR transmitter.

UNBELIEVABLY PRICED AT 3 for $12.00

*PL Registered Motorola trademark

More Details? CHECK-OFF Page 126
Space age communication equipment demands a crystal that meets all standards of technical advancement. Crystals that were acceptable some years ago do not meet present day specifications. As a general rule, your crystal must be selected from the best quartz... (no throw off cuts). Tight tolerances demand selected angles of cut. The x-ray is important in making this selection. The crystal should be preaged with stress cycling. It should be checked for frequency change vs temperature change. It must be checked for optimum spurious response. It should be calibrated to frequency with the correct oscillator. International Crystals are manufactured to meet today's high accuracy requirements. That's why we guarantee all International crystals against defective materials and workmanship for an unlimited time when used in equipment for which they were specifically made.

2 Rigs in one!

Comcraft's NEW
VHF Two-Band Transceiver for 2 and 1 1/4 meters with Digital Frequency Synthesis

The new CST-50 Two-Band Transceiver provides coverage of two complete amateur bands with all the features needed by most operators. Imagine! The two most popular VHF bands in one rig with Phase Locked Loop frequency synthesis. In the CST-50 all frequencies are generated digitally by reference to one highly accurate and easily adjustable crystal. As soon as a new repeater is on you can use it, no waiting for crystals. Write for further information.

- Covers entire 2 meter and 1 1/4 meter bands
- Covers MMRS, CAP and CID frequencies from 142 to 149.995 MHz
- All digital frequency synthesis with 5 kHz steps
- Lighted thumbwheels for night mobile operation
- No crystals to buy—ever
- Built-in repeater offsets of 600 kHz, 1 MHz, and 1.6 MHz
- 25 watts output on each band
- No transmitter turning across either band
- FM/MM receiver
- Low crystal filters
- Front mounted speaker
- PTT microphone and mobile mount included
- Operate on 12 with DC
- AC supply available
- Accessory connector for tone burst and tone coded squelch

an extraordinary combination of digitally synthesized receivers...

each with built-in capacity to satisfy a broad spectrum of singular applications.

ITT Mackay Marine 3020A and 3021A Radio Receivers feature solid state construction, dual conversion and super-heterodyne design providing continuous frequency coverage from 15kHz to 29.9999MHz. Frequency selection is accomplished by step tuning, while the 3021A Receiver uses sweep tuning. These receivers meet strict requirements of British MPT, German FTZ, Norwegian NTA, Dutch and Spanish PTT and Canadian DOC, and can be used wherever maximum reliability and ease of maintenance are required.

Write or call Ed Engebretson, General Sales Manager (K41QD), today for complete information on these two quality, high performance receivers.

ITT Mackay Marine, 2912 Wake Forest Road, Raleigh, North Carolina 27611. Telephone: (919) 828-4441.

**PD 301 PRESCALER**

with Power Supply

Kit $43.50  Assembled $55.50
Add $1.50 Postage & Insurance

Model PD 301 is a 300 MHz prescaler designed to extend the range of your counter ten times. This prescaler has a built-in preamp with a sensitivity of 50 mV at 150 MHz, 100 mV at 260 MHz, 175 mV at 300 MHz. The 95H90 scaler is rated at 320 MHz. To insure enough drive for all counters, a post amp. was built-in. The preamp has a self contained power supply regulated at 5.2V +.08%. (Input 50 Ohms, Output Hi-Z)

All prescalers are shipped in a 4" by 4" by 1½" cabinet. All are wired and calibrated.

March 1968 (first issue)  
FEATURED: 5-band SSB exciter, IC-regulated power supply, Remotely-tuned 10-meter beam, Transistor curve tracer, Double-balanced mixers.

May 1969  

August 1969  
FEATURED: Homebrew Parabolic Reflector, Solid-state Q-5er, Frequency calibrator with mos IC’s, New multiband quad antenna, Troubleshooting with a scope.

September 1969  
FEATURED: FM techniques and practices, IC power supplies, 1296-MHz varactor tripler, Tunable bandpass filters, Amateur microwave standards.

October 1969  
FEATURED: Hot Carrier Diodes, Low-cost Linear IC’s, Diversity antennas, solid-state 432-MHz exciter, Tropospheric duct communications.

November 1969  
FEATURED: Op Amps theory, selection & application, WWV receiver, Multiband antenna, Electronic key, Six-meter collinear.

June 1971  
FEATURED: A practical approach to 432-MHz SSB, FM carrier-operated relay, Audio AGC systems, Practical IC’s, Low-noise 1296-MHz preamp.

June 1972  
FEATURED: 5 Band solid-state communications receiver, FM repeater control, SSTV sync generator, microwave experimenting.

August 1972  
FEATURED: Frequency synthesizer for Drake R-4, 2304 MHz preamp, audio filters, RTTY Monitor scope, mobile touch-tone.

October 1972  
FEATURED: 4 channel spectrum analyzer, HF frequency synthesizer, all-band dipole, 160 meter vertical, multi-function IC’s.

December 1972  
FEATURED: Satellite communications, UHF swr bridge, RTTY monitor, receiver, FM channel elements, helical mobile antenna.

January 1973  
FEATURED: Matching networks, digital readout VFO, fm repeater recoder, six-meter preamp, tunable phase locked loop.

February 1973  
FEATURED: Communications receiver design, rf speech clipper, fm receiver scanner, Plessey SL600 integrated circuits, solid-state noise blanker.

March 1973  

June 1973  
FEATURED: Digital RTTY auto-start, fm repeater installation, micropower receiver, broad-band amplifiers, logic oscillators.

July 1973  
FEATURED: SSTV test generator, carrier operated relay, VHF receiver, two-meter frequency synthesizer, antenna matching.

HAM RADIO BINDERS  
Collector’s items deserve the best protection you can give them, and we know of no better than our handsome Ham Radio Binders. Bound in washable buckram and supplied with year labels to identify each volume. Each binder holds 12 issues.

$5.00 each 3 for $13.50

HAM RADIO BOUND VOLUMES  
Here is a handsome addition to your library. Twelve issues (a full year) of Ham Radio bound into a rugged, good looking, hard cover book. Certainly the most deluxe way to collect Ham Radio and perhaps the only way to acquire some out of print back issues. Years 1971, 1972, 1973 and 1974 available.

$14.95 each

FROM MURCH ELECTRONICS the UT2000A
THE ULTIMATE TRANSMATCH MULTIBAND ANTENNA 10 - 80 M

Similar to the one in Lew McCoy's article
July 1970 QST also 1972 Handbook

- Use with any coax or end fed random wire antenna, ideal for apartment dwellers
- 2 kW P.E.P. (1 kW continuous) 1:1 SWR to transmitter
- 10-80 continuous, including MARS
- Use with any wattmeter or SWR indicator
- Heavy duty throughout (4000 volt capacitors)
- Rotary Inductor with turns counter
  12" w 12" d x 5 1/2 h, 12 lbs shipping weight

FIELD PROVEN 4 years
- Sealed center insulator, 102 ft. wire, 30 feet heavy duty twin lead
- Coax fitting to connect twin lead to 52 ohm transmission line (68 feet or more, not included)
- Ready to use. Great on all bands without a transmatch. Even better with the Ultimate Transmatch

MODEL UT-2000A New price effective August 1, 1974

MURCH ELECTRONICS INC.
Box 35 Franklin Maine 04634 Phone 207-565-3312

NEW!

500 MHZ COUNTER

A smooth rhythmic feel—a slight but definite “break”—these are among the highly desirable features that make the operation of a Ten-Tec keyer a delightful experience. The KR50 paddle suspension employs ball bearings and adjustable electromagnetic forces to achieve the unique “soft touch” that means smoother, more articulate and relaxing QSOs for you. Write for details.

KR50
Top-of-the-line iambic squeeze keyer. Full dit and dah memo-
ding characters. Automatic weight correction vs speed. Over-ride touch switch and monitor oscillator. 117 VAC or 6 to 14 VDC.

K W BALUN KIT STILL ONLY $5!

The AMIDON Toroid Balun Kit makes a modern, compact antenna transformer that can be wired for either 417 or RTTY performance. The balun is ideal for use between a coaxial feedline and a balanced antenna. It reduces coax radiation and permits the antenna to be moved around without the danger of touching the feedline and tripping a line. The balun will also serve as an isolation device and removes the capacity of the coax from the antenna. Also included in this kit is a dipole antenna for tailgaters. Admission $2, or $4 for those wanting to tailgate. Contact K3RUQ.

TELETEYPEDRITERS PARTS, gears, manuals, supplies, tape, foroids. SASE list. Typetronics, Box 8873, Ft. Lauderdale, Fl. 33310. Buy parts, late machines.

MANUALS for most ham gear made 1940-65, some earlier. Send SASE for specific quote. Hobby Industry, WOJJK, Box H-646, Council Bluffs, Iowa 51501.

TELETEYPEDRITERS FOR SALE — Model 28 printer, keyboard, cabinet, loop supply, all complete. Also, military R-330 receiver and URA-17A converter. All equipment like new. Make best offer. Floyd Martin, WA4VVA, Rt. 3, Box 56-D, Pensacola, Fla. 32503, (904) 477-9684.

LICENSE GUIDES

We don't know if it's Restructuring, the economy, or just a renewed interest in amateur radio, but more radio license guides of all types have been purchased this year than ever before. Here's your chance to get on the bandwagon. We've got 'em all and they're in stock for immediate delivery.

THE RADIO AMATEUR'S LICENSE MANUAL from ARRL

This study guide and reference book covers all grades of amateur licenses. Complete with typical questions and answers to typical FCC amateur examinations. Also contains the amateur regulations. Certainly the most used publication of this type anywhere.

Even if you're limited to just a few square feet of real estate, you've got room for a high performance Hy-Gain multi-band vertical. Great coverage in minimum ground space, or roof mount for optimum performance using Hy-Gain 12RMQ or 14RMQ Roof Mount/Radial Kit. All these antennas are entirely self-supporting.

18HT Hy-Tower 6 thru 80 meters
Unquestionably the finest multi-band omnidirectional vertical antenna available. Entire structure is radiating element with automatic band switching. All hardware iridited. Unique stub decoupling for 50 ohm input on all bands. Also operates 160 meters with loading coil. Takes maximum legal power with ease. No roof mount. Ht. 50'. Wt. 100 lbs.
Order No. 182

18AVT/WB 10 thru 80 meters
True ¼ wave resonance on all bands, automatic band switching and optimum wide-band performance combine to make the 18AVT/WB one of the most popular amateur antennas. Three heavy duty Hy-Q Traps, top loading coil, extra heavy duty construction. Roof mount with 14RMQ. Ht. 25'. Wt. 10.7 lbs.
Order No. 386

18V 10 thru 80 meters
Low cost, high efficiency, and quality construction make the 18V ideal for budget-conscious HAMS. Easily tuned to any 10-80 meter band by adjusting feed point at base inductor. Highly portable. Roof mount with 14RMQ. Ht. 18'. Wt. 4.6 lbs.
Order No. 193

14AVQ/WB 10 thru 40 meters
Improved for even greater wide-band performance! Three separate Hy-Q Traps with oversize coils for extremely high ¼ wave resonance on all bands. Outstanding low angle radiation pattern. Roof mount with 14RMQ. Ht. 18'. Wt. 8.6 lbs.
Order No. 385

12AVQ 10, 15 and 20 meters
Inexpensive tri-band vertical for performance with minimum investment in space and equipment. Low radiation angle. Roof mount with 12RMQ. Ht. 13'6". Wt. 6.8 lbs.
Order No. 384

For prices and information, contact your local Hy-Gain distributor or write Hy-Gain.

Hy-Gain Electronics Corporation, 8601 Northeast Highway Six, Lincoln, NE 68507; 402/464-9151; Telex 48-6424.
Branch Office and Warehouse, 6100 Sepulveda Blvd., #322, Van Nuys, CA 91401; 213/785-4532; Telex 65-1359.
Distributed in Canada by Lectron Radio Sales, Ltd., 211 Hunter Street West, Peterborough, Ontario.
THE ELECTRONIC SCIENTIFIC SLIDE RULE WITH FUNCTIONS TO ENABLE YOU TO SOLVE ALMOST ANY PROBLEM, ANYWHERE, ANYTIME! JUST PRESS THE KEYS.

ORIGINALLY PRICED AT $179.95 - NOW ONLY $109.95 or $89.95 as a kit with completed and pretested electronic boards including instructions for assembly.

COMPLETED UNITS AND KITS FURNISHED WITH CARRYING CASE, NI-CAD RECHARGEABLE BATTERIES AND CHARGER.

ONE (1) FULL YEAR WARRANTY.

The SI-36 is Dev-Tronics first in a family of scientific calculators for the engineering and scientific fraternity featuring fully depressed keyboard with detent and click. It is a precision built, quality calculating machine with advanced design and algebraic keyboard entry (as you would normally write an algebraic problem) with the capability of solving detailed business problems and complex scientific arguments. Because of the designed-in flexibility of the SI-36 calculator to operate off throw-away and/or rechargeable batteries, you never have a loss of the use of this calculator when you are away from your charger. Merely replace your rechargeable batteries with commonly available 1.5 volt penlite cells to restore normal operation.

BROAD RANGE OF APPLICATION: Computes natural and common logs and antilogs. It calculates sine, cosine and tangents of trigonometric calculations and their inverses. Scientific notation and display range from 1.0X10^-99 to 9.999999999X10^99. For ease of entry it features special (2 level) parentheses keys, will handle non-scientific notation with a 10 digit mantissa, 2 sign digits and 2 scientific notation digits.

This is an amazing calculator costing much less than comparable machines priced to $225.00 But, don’t compare price; compare features and functions.

PUT MORE REACH IN YOUR FM WITH A TEMPO RF POWER AMPLIFIER FROM HENRY RADIO

With the simple installation of a Tempo VHF or UHF power amplifier you can extend the range of your mobile FM transmissions far more than you dreamed possible.

They operate in the VHF frequency range of 135 to 175 MHz and the UHF range of 400 to 512 MHz, offering a wide choice of power outputs. They effectively increase the range and clarity of two-way communications under all operating conditions, can be used with hand-held units, low or medium power mobile transceivers or in repeaters.

Altho moderately priced, Tempo amplifiers offer meaningful savings in new equipment costs and greater efficiency in either new or existing communications systems. Are compact, reliable, foolproof to operate and are available for immediate delivery.

Modern solid state technology is used throughout, along with conservatively rated components to assure the highest possible reliability. Microstrip design on glass epoxy circuit boards give added resistance to damage from shock or prolonged vibration.

FCC type accepted models also available.

Available at select Tempo dealers throughout the U.S.

High performance at low cost...
the Tempo FMH

Excellent performance at low cost. The Tempo FMH is a compact two watt VHF/FM transceiver offering high quality performance and features usually found on more expensive units. Six channel capability, completely solid state, lightweight and reliable. A perfect companion for the Tempo RF power amplifiers. Plugged into the amplifier, the handheld FMH becomes a mobile with much greater power. $199.00

FMH-MC for marine & commercial service also available.

The Tempo 6N2
Meets the demand for a high power six meter and two meter power amplifier. Using a pair of Eimac 8874 tubes it provides 2000 watts PEP input on SSB and 1000 watts input on CW and FM. Completely self-contained in one small desk mount cabinet with internal solid state power supply, built in blower and RF relative power indicator

$795.00
2 meter only
$695.00
